An account is given of the preparatory measures taken to ensure that the Act should come into effective operation on January 1st, 1931. As recorded in these columns last year, a largely attended conference of persons interested was held at the Central Hall, Westminster, and following this a circular memorandum was issued to all local authorities, summarizing the provisions of the Act and making suggestions for the steps necessary to give effect to them. Rules were drawn up under Section 15 of the Act and the Third Schedule, and these were consolidated with the existing Lunacy Rules of 1925, thus bringing all Rules under the Lunacy and Mental Treatment Acts together in a single code. Early steps were also taken to bring to the notice of voluntary hospitals the opportunity which the Act affords them of co-operating in the treatment of mental illness. Conferences were held and a special memorandum was issued. The approval of medical practitioners for the purpose of making recommendations under Sections 1 (3) and 5 (3) presented difficulties, and a committee was appointed, with Sir John Rose Bradford as chairman, to advise the Board on questions of principle. The recommendations of this committee were adopted, and up to March 31st the Board had approved 2,209 medical practitioners. In accordance with Section 11 of the Act the Board itself has been reorganized, and as from January 1st, 1931, it has consisted of five Senior Commissioners, mainly employed at headquarters. The bulk of the visitation will in future devolve upon the Commissioners, medical and legal, who have been appointed by the Board with the approval of the Minister of Health.

An inquiry as to the progress made up to the end of February of this year in the provision of out-patient, voluntary, and temporary patients, showed very unequal results in different areas, but the development of out-patient clinics is already most gratifying.

INSTITUTIONAL ACCOMMODATION

On January 1st, 1931, the number of notified insane persons under care in England and Wales was 144,161. The increase in the number of patients in public mental hospitals during 1930 was 2,410. While this increase may be regarded as normal and representing approximately the rate of increase which is to be anticipated for some years to come, it does not indicate any real increase in the incidence of mental disorders. Although for reasons set out in its report the Board sees no ground for pessimism when the question is regarded purely from the public health point of view, the annual increase of mental disorder is a matter of grave concern in its bearing upon the adequacy of existing institutional accommodation. The hope was entertained that this dangerous position would have been substantially relieved by the reallocation of Poor Law buildings transferred to local authorities under the Local Government Act, 1929, "but, when every allowance is made for the possibility of relieving in this way the pressure on the public mental hospital, it is clear that many authorities are faced with the urgent need of providing new hospitals." The need of beds is so acute that new building cannot be further postponed without grave risk. "Even as a temporary expedient overcrowding is dangerous. It imposes an intolerable strain on the nursing staff, and it adds greatly to the risk of epidemic disorders."

One of the most important questions engaging the attention of the Board is that of research. Recognizing that the number of hospitals able to carry out independent research must be limited, the Board welcomes the provision, in the Mental Treatment Act which empowers local authorities to contribute to research undertaken by other bodies, such as universities. To advise it on means for co-operative research the Board is taking steps to establish an advisory committee on which local authorities may be represented. It is hoped in this way to draw up a comprehensive programme of research into the causes of mental disorder, without which no great advance can be made in the application to mental disorder of the principles of preventive medicine.

Notwithstanding efforts made by many hospitals to improve the lot of their nurses, difficulty is found in securing enough probationers. The shortage is more acute in some hospitals than in others, but few are so happily placed as to have a waiting list. The Board doubts whether the scope for real nursing work in public mental hospitals is adequately appreciated.

SEDATIVES IN MENTAL HOSPITALS

For several years the authorities of all mental institutions have supplied the Board with particulars with regard to the use of sedatives, giving the quantities used annually and the average number of sleeping draughts administered each night. The data supplied revealed a wide variation in practice.

"There is clearly no consensus of opinion in respect to the value of sedatives in the treatment of mental illness. Some institutions use hardly any, but it can be said that in no case are the quantities used excessive. There is also little agreement regarding the value of individual drugs. Some given freely in one hospital are rarely, if ever, used in another. It is in no critical spirit that we draw attention to this divergence in practice, but we suggest that the subject is one that needs further study and investigation. Research is much wanted, so that it may be possible to define more clearly the conditions under which sedatives should be prescribed. It seems clear that order and tranquillity of mental hospitals bear little relation to the extent to which sedatives are used."

[1] The Seventeenth Annual Report of the Board of Control, for the Year 1930. Part I. London: H.M. Stationery Office. 1931.

A revised list has been published of the sanatoriums and other residential institutions approved by the Minister of Health for the treatment of persons suffering from tuberculosis and resident in England and Wales. As in previous years the names of the administrative counties and county boroughs in which the institutions are situated are given, with notes about such matters as limitations in respect of certain forms of the disease and of the sex of patients. The list is obtainable from H.M. Stationery Office, price 4d. net.

Medical News

The annual dinner of the British Medical Association will take place at the Grand Hotel, Eastbourne, on Thursday, July 23rd, at 7.30 p.m. As the accommodation is limited, it is desirable that members wishing to have tickets reserved should notify the Honorary Secretary, Eastbourne Meeting, Avenue House, Eastbourne, at the earliest possible date. Tickets will be allotted strictly in order of application. Vouchers entitling members to take advantage of the facilities offered by the railway companies of Great Britain can be obtained on application to the Financial Secretary of the Association. The companies will issue return tickets available until July 27th at the ordinary single fare and a third for the double journey.

In connexion with the British Medical Association meeting at Eastbourne, a medical missionary breakfast will be held, under the auspices of the Medical Prayer Union, on Friday, July 24th, at Stewart's Restaurant, Victoria Place, at 8.30 a.m. The chair will be taken by Dr. W. G. Willoughby, President, B.M.A. An address will be given by Dr. A. R. Cook of Uganda. Intimation of intention to be present will be welcomed by Dr. Victor G. Williams, 6, College Road, Eastbourne.

Founder's Day will be celebrated at Epsom College on Saturday, July 25th. There will be service in chapel at noon, and prizes will be given away by the Bishop of Guildford at 2.45 o'clock. After tea there will be an assault-at-arms, and in the evening a performance of *Patience* by the choral society. On Saturday, October 3rd, Lord Dawson of Penn, P.R.C.P., will open the new school sanatorium.

Detailed information about the lectures and demonstrations arranged for next week by the Fellowship of Medicine and Post-Graduate Medical Association will be found at page 48 of the *Supplement*. A course in medicine, surgery, and the specialties will be given at the Miller General Hospital from July 20th to August 1st; fee £3 3s. A course in urology will be given at the All Saints' Hospital, Vauxhall Bridge Road, from August 4th to 29th, fee £2 12s. 6d. From August 17th to 29th a course in diseases of children will be given at the Queen's Hospital for Children, Hackney Road; fee £2 2s. Courses in September will include diseases of the chest at the Brompton Hospital, psychological medicine at the Bethlem Royal Hospital, diseases of infants at the Infants Hospital, ophthalmology at the Central London Ophthalmic Hospital, general medicine and surgery at the Westminster Hospital, followed by a similar course at the Metropolitan Hospital. Syllabuses and tickets for all the courses may be had from the Fellowship of Medicine, 1, Wimpole Street, W.1.

A meeting of the Osler Club was held in London on Sunday evening, July 12th, to celebrate the eighty-second anniversary of Sir William Osler's birthday. Dr. William Stobie, Mayor of Oxford, delivered the fourth Oslerian Oration, in which he skilfully blended the interesting narrative of Osler's inspiring leadership in the tuberculosis campaign in Oxfordshire with a moving account of Osler as clinician, chief, and friend. Dr. A. Salusbury MacNalty of the Ministry of Health proposed, and Dr. A. P. Cawadias seconded, a vote of thanks, and Sir Percival Hartley briefly spoke in the discussion. Letters and messages had been received from absent friends: Professor J. F. Fulton of Yale University, Dr. Henry R. Viets of Boston, Dr. Vilhelm Maar of Copenhagen, Sir Arthur Keith, and Professor Grey Turner. Among those present were Sir D'Arcy Power, Dr. J. D. Rolleston, Dr. K. R. Hay, Professor D. Fraser-Harris, and Mr. Arnold M. Muirhead, whose recent *Memoir* of Lady Osler was displayed among the exhibits.

A quarterly court of the directors of the Society for Relief of Widows and Orphans of Medical Men was held on July 8th, when Dr. W. Culver James, senior vice-president, was in the chair. The death of an annuitant was reported. She had been in receipt of grants since 1920 and had received £787 10s.; her late husband had paid £52 10s. in subscriptions. £2,075 was voted for the half-yearly grants to the fifty-two widows and seven orphans on the books, and £123 15s. was voted as special grants for six orphans, to enable them to continue their education, inasmuch as they had reached the age of 16, when the ordinary grants ceased. A rebate of income tax amounting to £820 13s. 8d. had been received from the Inland Revenue for the year ending April, 1931. Relief is only given to the widows and orphans of deceased members. No widow with an income exceeding £125 per annum is eligible for relief. Membership is open to any registered medical man who at the time of his election is resident within a twenty-mile radius of Charing Cross. After election a member need not remain within this area. Full particulars may be obtained from the secretary at the offices of the society, 11, Chandos Street, Cavendish Square, W.1.

The annual general meeting of the Medical Society of Individual Psychology was held, after a dinner, at the Florence Restaurant, on July 9th. Dr. O. H. Woodcock, the outgoing chairman, referred to the great progress made during the year, marked as it was by a visit from Dr. Adler in January. The financial position was strong, and the membership had quadrupled during the last nine months. A series of publications had been successfully inaugurated by "The case of Mrs. A" (a lecture-demonstration by Dr. Adler), and it was proposed to continue the issues at least quarterly. The publications are to be distributed gratuitously to all members and associates of the society; non-members will be able to obtain copies, through booksellers, from the publishers, the C. W. Daniel Company. Dr. W. Langdon Brown was elected chairman for the ensuing session, which opens in October next, with Dr. Crookshank as editor, and Dr. Hilda Weber as assistant editor of the publications. Dr. Thomas E. Lawson (to whom all applications for membership and information should be addressed, at 11, Chandos Street, W.1) was re-elected honorary secretary and treasurer.

On the occasion of his retirement from Moreton-in-Marsh, Gloucester, where he has practised since 1888, Dr. R. E. B. Yelf was presented by his friends and patients with a watch and a cheque for £106, as a mark of their esteem, and Mrs. Yelf was given a portable wireless set.

The celebration of the fourth centenary of the Collège de France began on June 18th, when Professor H. Vincent, member of the Institut de France and of the Académie de Médecine, delivered an address on Claude Bernard and the Collège de France.

The first International Congress of Mediterranean Hygiene will be held at Marseilles, under the presidency of Dr. Marchoux, from September 20th to 25th, 1932. Further information can be obtained from the general secretary, Dr. Violle, 40, Allées Leon Gambetta, Marseilles, or from Dr. Broquet, 195, Boulevard St. Germain, Paris, 7e.

The issue of *Le Scalpel* for July 4th is devoted to the account of the eleventh annual congress known as the Journées Medicales, held at Brussels from June 20th to 24th.

The issue of the *Gazette des Hôpitaux* for June 17th is devoted to tropical diseases, in anticipation of the International Colonial Medical Congress to be held in Paris from July 22nd to August 4th.

Further reports of subcommittees of the Pharmacopoeia Commission have been published lately by authority of the General Medical Council (44, Hallam Street, W.1). No. 5 (price 1s.) deals with the preparation of sterile solutions for injection; No. 6 (1s. 6d.) comprises the second report of the Pharmacy Subcommittee; No. 7 (1s.) is the report of the subcommittee on ampoule glass.

Dr. Laignel-Lavastine, senior physician to the Hôpital de la Pitié, and secretary of the International Society of the History of Medicine, has been nominated professor of the history of medicine in the Paris Faculty in succession to Professor Menetrier.

Sir Hilarion M. Fernando, M.D., has been reappointed a member of the Executive Committee of the Island of Ceylon.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W C 1, on receipt of proofs

All communications with reference to ADVERTISEMENTS as well as orders for copies of the *Journal* should be addressed to the Financial Secretary and Business Manager

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM* 9861, 9862, 9863 and 9864 (internal exchange, four lines)

The **TELEGRAPHIC ADDRESSES** are

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology, Westcent, London*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements etc), *Articulate Westcent, London*

MEDICAL SECRETARY, *Medisecra Westcent, London*

The address of the Irish Office of the British Medical Association is 16 South Frederick Street Dublin (telegrams *Bacillus Dublin*, telephone 62550 Dublin), and of the Scottish Office 7, Drumsheugh Gardens Edinburgh (telegrams *Associate, Edinburgh*, telephone 24361 Edinburgh)

QUERIES AND ANSWERS

Oxaluria

DR BLACKBURN (Beckenham) writes In reply to "Inquirer" (Kenya), the conditions causing an excretion of oxalate crystals in addition to exogenous sources, are achlorhydria or diminished acidity, with resulting fermentative digestive disturbances A diet poor in calcium and rich in magnesium should be ordered An increase in meat is advisable, as it raises the acidity of the urine Tomatoes and asparagus should be avoided, and gelatin is inadvisable, as it is a precursor of oxalates A dose of calomel once a week, followed by mag sulph, is the best medicine to order Plenty of fluids should be taken and Contrexeville water, containing acid carbonates, is valuable

Income Tax

Car Allowance

"A F" bought a new car in April, 1930, "and was allowed replacement allowance," based on a cost of £350 for the new car For 1931-32 he claimed depreciation allowance—that is, 20 per cent of £350=£70—but has been allowed only £28 at 20 per cent = £6, that allowance being based on the written down value (? of the old car) brought forward

*** Depreciation allowance is made by way of anticipation of the cost of replacement, and it has been decided that, as for the same financial year, a taxpayer cannot claim an actual replacement cost *and* a depreciation allowance in respect of the same kind of equipment "A F's" liability for 1931-32 is based on his earnings for 1930-31, and it is understood that in computing the amount of those earnings he deducted the cost of car replacement If so, and if he were allowed depreciation for 1931-32, the tax for that financial year would be reduced by both (alternative) forms of allowance We suggest that he should ask the inspector of taxes whether he will be prepared to admit a claim to depreciation on his car for 1932-33, when the tax payable will no longer be affected by the cost of replacement deduction

LETTERS, NOTES, ETC.

Operation for Cataract

Personal Experiences

Lieut Colonel W K HATCH, F R C S, I M S (ret), writes The question of operating for cataract when one eye is in a more advanced condition of disease must I think, be decided after due consideration of the condition in each case In my own case the history is approximately as follows In 1929 I was told by Lieut-Colonel R H Elliot, whom I consulted, that I had a definite cataract in the left eye and commencing disease in the right eye I therefore had an iridectomy performed by him in April, 1929, and would have had the extraction in the same year but severe bleeding from duodenal ulcer prevented the operation taking place until the end of May, 1930, the operation being most successful During that summer I was able, using my right eye, to play bowls and to do some fly fishing fairly comfortably Though I could see splendidly with the glasses for the left eye I did not use them much indoors Early this year I could still read clear print in a good light and even decipher my own writing (which is rather difficult to do), but found that I could no longer play bowls or see my line when fishing, except very occasionally, and was unable to do delicate operations, such as tying on flies, etc I therefore had to fall back on the operated eye, which I fortunately had in reserve By this time, too, I was better able to judge distances and to walk with more facility At the end of May, 1931, Colonel Elliot performed iridectomy on the right eye, and the date of extraction now remains to be settled I have no doubt that I could shoot all game using the operated eye, but as it is the left, I do not think it worth while to learn how to shoot from the left shoulder, or have a cast made in the stock of my gun As it takes longer than one would expect to get accustomed to cataract glasses, and to judge distances get over the peculiar giddiness one feels at first, and the change of colour of some objects, faces, and clothes, it seems to me most necessary to operate early on the worst eye It will then be ready to take over charge when the best eye fails I am thankful that this was done in my case, as I can still enjoy my usual pastimes as well as I did before operation

Nord-Sud Tour in Italy

We are asked by the London office of the Italian State Railways (16, Waterloo Place, S W 1) to say that there are still some vacancies in the medical tour to Italian resorts and spas in September and October next, referred to by a correspondent on March 28th (p 568)

West African Medical Staff Dinners

"W A M S" writes The effort to revive the annual dinner of the W A M S, which used to be held before the war, has been unsuccessful, apparently owing to apathy on the part of those concerned This is to be regretted Such dinners tend to foster the spirit of cohesion and *esprit de corps* among the officers in the Service, they also afford opportunities for meetings between past and present members of staff, and between the staff and officials of the Colonial Office and prominent medical men, some of whom in each category, are usually present At this time of year most organized units—the regiments, the I M S, the R A M C, and others—are holding their annual dinners, the W A M S seems to be almost the only unit that does not follow the custom It is to be hoped that the matter will not be allowed to drop, but that some energetic officer on the active list will, later on, try to revive the dinners, with more success than has attended the present effort

A Warning

The Chief Constable of Birkenhead informs us that a man recently called on a doctor in that borough pretending to represent the Lady Haig Fund for Students Disabled in the Great War, and trying to sell Harris tweeds fountain pens, etc, and filing cabinets for the use of panel doctors The man is described as follows 26 to 28 years, height 5 ft 10 in, fair hair, curly at back, fresh complexion, *clean shaven, dressed in navy blue mackintosh*, carries a walking stick, and walks with a limp

Disclaimers

DR EDGAR CYRIAX (London, W) writes My attention has been drawn to a book entitled *The Quest for Health*, which has just been published It contains a number of statements, many of which are entirely erroneous, about certain methods of treatment practised by myself and my wife, Dr A Kellgren Cyriax This was done without my knowledge and consent

DR G EDHOLM (London, S W) also writes to say that his name appears in *The Quest for Health* without his authority

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 47, 48, 49, 50, 51, 54, and 55 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 52 and 53

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 17

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

54 Trigeminal Neuralgia during Serum Administration

R. F. VACCAREZZA (*Rev. Sud-Amér. de Méd. et Chir.*, May, 1931, p. 465) describes the case of a woman who developed facial tetanus four days after pricking her chin with a rose thorn; she recovered after receiving 180,000 units of serum. Seven days after the first injection a very severe serum reaction ensued, with vomiting, articular pains, and haematuria. During convalescence she had very painful neuralgia, involving all the branches of the facial nerve; there was also some pain in the occipital and nuchal regions, showing that the cervical roots were also involved. The severe pain persisted for several weeks, and then gradually subsided, but after two years there still remained hyperaesthesia of the side of the face affected (the opposite to that of the original wound), accompanied by twitching of the muscles of mastication and occasional fleeting pains. Vaccarezza considers that the neuralgia is a sequel of the serum reaction, and not of the original tetanic infection; he can find no record of neurological complications following tetanus other than of a paralytic nature. He alludes to the rarity of sensory nervous disturbances following serum administration, the motor forms being much more usual, and he quotes instances of both forms following the injection of antitetanic and other serums.

55 Hypoglycaemia accompanying Pancreatic Hypertrophy

According to A. W. PHILLIPS (*Journ. Amer. Med. Assoc.*, April 11th, 1931, p. 1195) hypoglycaemia appears to be due primarily to hepatic, endocrinal, or pancreatic pathological changes in the liver, the endocrine glands, or the pancreas, and is seen in various diverse conditions. A case is recorded which clinically appeared to be uraemia with hypoglycaemia; the necropsy revealed hypertrophy of the islands of Langerhans and nephritic changes. The relation of a marked retention of nitrogen and creatinine to the urinary and post-mortem renal findings indicated that the exciting cause of death was probably of renal origin. Both the pancreatic and renal changes may have been present for some time as entirely separate pathological conditions. Phillips believes that the hypertrophy of the islands of Langerhans, with probably increased insulin production, was the etiological factor in the hypoglycaemia of the present case, and that such hypertrophy explains some mild cases of chronic hypoglycaemia of long duration which are relieved by a diet high in carbohydrates. Periods of high sugar ingestion or temporary dysfunctioning of a sugar-regulating mechanism, other than the pancreas, may conceivably provoke hypertrophy of the islands, and a hyperinsulinism which continues after removal of the unusual stimulus.

56 Vaccination in the Newborn

L. LUMEZ (*Arch. f. Kinderheilk.*, April, 1931, p. 124) states that vaccination was performed on sixteen newborn children aged from 4 hours to 3 days, and on two children aged 8 and 9 days respectively, with lymph which had been in the ice-chest between six and eight weeks. As a general rule the course of vaccination was more pronounced in the newborn, who showed well-marked allergic reactions. In contrast with older infants the newborn sometimes showed a delay in the appearance of the vaccine vesicle (sixth to seventh day), and more rarely a delay of two or three days in the appearance of the vaccine pustule. The newborn also showed an increased tendency to the formation of supplementary vaccine reactions in 6 out of 20 cases, which were not seen in any of 20 controls. The newborn, like the older infants, showed a vaccinal reaction in the blood. The first vaccinal leucocytosis was in many cases reduced or annulled by the predominant allergic tendency to leucopenia in the first week. On the other hand, the second leucocytosis was favoured or considerably increased by the tendency of leucocytosis in the second week of life; there might, however, be no blood reaction at all. The mild local cause of the lymph reaction in the newborn is partly due to the peculiar mode of reaction of the young to infection or reinfection.

57 Focal Infection in Acute and Chronic Nephritis

O. RÖMCKE (*Nordisk Medicinsk Tidskrift*, May 29th, 1931, p. 344) reports from the Ullevaal Hospital in Oslo 13 cases of more or less prolonged nephritis in which treatment of a focal infection had a beneficial effect on the nephritis. In one case an outbreak of eczema was followed by a pustular dermatitis, the development of which coincided with the appearance of blood in the urine. Haematuria and albuminuria persisted after the skin condition had cleared up, and after several carious teeth had been removed. The patient also suffered from chronic bilateral otitis media, and when a radical operation was performed on one side, and more conservative treatment was prescribed for the other side, the haematuria, which had then persisted for eight months, cleared up in three weeks. In another case, complicated by pulmonary tuberculosis, the haemorrhagic nephritis from which the patient was suffering proved refractory to dietetic treatment and rest in bed. After the signs of nephritis had remained unchanged for four months an infected tooth was removed, and fourteen days later the urine was normal. In another case, in which the nephritis had lasted for a year, tonsillectomy was followed in eight days by the disappearance of all the abnormal elements from the urine.

Surgery

58 Dilating the Pylorus

M. EINHORN (*Med. Journ. and Record*, June 3rd, 1931, p. 531) gives notes of two cases in which the bloodless method of stretching the pylorus for benign obstruction gave excellent results. The first patient, a man aged 49, had complained for seven years of symptoms suggestive of duodenal ulcer; an *x*-ray examination appeared to confirm this, though an exploratory laparotomy was negative. He lost weight and became very weak. The barium meal showed immense dilatation of the stomach, absence of the cap, and the presence of a six-hour and twenty-four-hour retention. After duodenal feeding for three weeks the pyloric dilator with a bead-string guide attachment was swallowed, and the pylorus stretched the next day to 50 F. The patient was soon able to take ordinary food without discomfort, and a few months later reported feeling perfectly well with a gain of 30 lb. in weight. The second patient, a man aged 37, complained of frequent attacks of epigastric pain which were relieved by alkalis; *x*-ray examinations showed a prolapsed and dilated stomach with a six-hour gastric residue, and a small deformed cap. A diagnosis of duodenal ulcer with commencing pyloric obstruction was made and duodenal feeding began; after three days nourishment was given by mouth, the pylorus being stretched to 60 F., and four days later to 70 F. He reported later that he was perfectly well, was able to take food without any discomfort, and had gained 15 lb. in weight. Einhorn remarks that this method of stretching the pylorus is a comparatively easy and harmless procedure. It is specially indicated in cases of severe pylorospasm and commencing benign pyloric stenosis occurring in feeble patients, in whom an open operation is contraindicated.

59 Arterial Embolectomy

C. ROBERTSON, A. E. MOORE, and D. ROBB (*Journ. of the College of Surg. of Australia*, March, 1931, p. 360), who discuss the literature, etiology, diagnosis, and treatment of arterial embolectomy, conclude that cardio-vascular disease is the commonest causative factor; next in frequency come surgical operations, parturition, and cardio-renal disease. A healthy, athletic man, aged 31, complained of pain at the base of the right thumb and weakness of grip, the condition extending over five months. The onset was abrupt; while driving a car the patient had sudden pain in the wrist, with weakness of the hand, and tingling in the fingers. This condition persisted for five months. On examination there was swelling of the soft parts on the dorsal aspect of the first interosseous space, and tenderness at the base of the thumb metacarpal. There was no muscular wasting or sign of nerve involvement. The radial pulse could not be felt, and an *x*-ray examination negatived any disease or traumatic lesion. A diagnosis of unabsorbed subperiosteal haemorrhage from some unremembered injury was made, and exploration was advised. The hand and forearm were exsanguinated with an Esmarch bandage during open ether anaesthesia. On cutting down at the base of the thumb a recent thrombosis in the radial artery was found; the artery was opened, and half an inch of dark red, non-adherent clot was expressed. The walls appeared healthy. The cut ends of the artery were ligated, and the wound was closed. The pain was considerably relieved by the operation. General examination revealed nothing that might cause an embolus. Four months later the hand had improved and there was faint pulsation in the radial artery at the wrist. The first interosseous muscles were tender. Thirteen months after the operation the hand was practically normal.

60 Cancer in General Practice

C. E. L. BURMAN (*Journ. Med. Assoc. of South Africa*, May 23rd, 1931, p. 311), recording observations on cancer in general practice, emphasizes the fact that successful treatment rests upon an early recognition of the precancerous stage—the stage of conflict between the transition of the connective tissue cells and that of the cancer cell. In spite of the success that has attended the use of radium, surgical removal should be undertaken where possibilities of cure are evident, even if it entails some scarring or disfigurement. The primary good results following the employment of radium in skin epithelioma renders it essential, however, to advise such treatment in these cases before resorting to surgery; but a ten-year period of non-recurrence is necessary before the possibility of surgical intervention can be finally abandoned. Radium treatment in cancer of the breast is promising, but where the tissues are bathed in physiological secretions, as in gastric, urinary, and brain cancer, the sequels are not so good; columnar and transitional epithelial tissues appear to be more resistant to radium. In combating the disease deep therapy and *x* rays are of value. For the early recognition of the precancerous stage it is important to educate the public to seek advice for any departure from normal health, for the appearance of abnormal skin growths, and for the persistence of ulcers showing no signs of healing.

61 Appendicitis on the Left Side

R. BONNAUD (*Thèse de Paris*, 1931, No. 128), who records 48 cases in patients aged from 5 to 62 years, five of which are original, states that appendicitis on the left side is to be suspected whenever pain and the signs of inflammation appear from the first on the left of the middle line. The displacement of the appendix is due to total or partial inversion of the viscera, excess or defect of the migration, rotation, descent, and fixation of the caecum, or to excessive length of the appendix, and a transverse and inward passing of the organ. Pain on the left side of the abdomen, however, has frequently been noted in cases where the appendix is in its normal position. On the other hand, appendicitis on the left may have as its sole symptom pain on the right side. In view of the fact that appendicitis on the left is more frequent than is generally supposed, Bonnaud recommends a radioscopic or radiographic examination to determine the position of the caecum and appendix before operation, whenever it is possible. If the correct diagnosis is made, the prognosis is no worse than in appendicitis on the right side. The technique of the operation differs little from that employed in ordinary appendicitis; the incision should be made on the left side or in the middle line in cases of doubt.

Therapeutics

62 Treatment of Collapse

E. HOLZBACH and E. KOLLORS (*Munch. med. Woch.*, May 22nd, 1931, p. 875) have made a long search for an ideal drug for use in the treatment of collapse. Such an agent must increase the venous return to the heart from the splanchnic reservoir; at the same time it must act as a cardiac stimulant, and ensure efficient emptying during systole. Adrenaline and ephedrine have the peripheral effect without much direct cardiac action, the latter working more slowly but for a longer period than the former. The addition of pituitrin (or, better, vasopressin) increases the duration of the effect still further, while strophanthin has the desired central (cardiac) action. A combination was therefore tried in animal experiments; it was found that it successfully combated collapse produced by such agents as histamine, arsenic, peptone, and bacterial toxins. The final composition of the mixture was: adrenaline, 0.001 mg.; vasopressin, 0.05 unit; strophanthin, 0.003 mg.; ephedrine, 0.1 mg., for each kilogram of weight. This is now being marketed in ampoules, each of which is adequate for a 60 kg. patient. The mixture should be diluted with 10 c.cm. or more of saline or glucose solution, and be given intravenously very slowly. The clinical results are described in the case of a series of patients suffering from various types of severe collapse, and they are very favourable, the pulse, colour, temperature of the extremities, and the general condition improving immediately. The effect lasts for some hours, and after this the injection can be safely repeated if necessary.

63 Carbon Dioxide Inhalation in Hiccups

L. A. GOLDEN (*New England Journ. Med.*, June 4th, 1931, p. 1183) recalls Yandell Henderson's emphasis on the value of a 5 per cent. strength of carbon dioxide in the inspired air in arresting post-operative hiccup. Sheldon had noted that this effect was in many cases permanent. The present author has therefore used the method for the relief of hiccup of the milder kind, occurring in daily life. An ordinary paper bag of medium size is placed over the patient's face, and he breathes in and out of it steadily. In a few minutes the percentage of CO_2 is sufficiently high to have a therapeutic effect, and the hiccup ceases. In one of his cases there had been continuous hiccup for two days, with stoppage of feeding and sleeping; rebreathing by this simple method arrested the spasms in four minutes. In Golden's cases the time required by patients for relief ranged between three and six minutes; if recurrences occurred, these were easily treated along the same lines by the patients at home.

64 Gold and Sulphur in Tuberculous Adenitis

R. HUGUENIN, MYRIAM LIBERSON, and YVES DUPONT (*Presse Méd.*, June 6th, 1931, p. 833) report gratifying success in the treatment of numerous cases of cervical and axillary tuberculous glands by means of gold. They found that larger doses of gold could be given in these cases than in pulmonary patients, and they were able to avoid almost completely any ill after-effects or toxic complications by arranging for the simultaneous administration of liver extract. The authors stress three points.

Pure gold is not nearly so efficacious as a compound of gold and sulphur, which can be injected intravenously. Larger doses, quickly reaching 0.75 to 1 gram a week, should be given in two doses, or even one dose, until a total of from 6 to 10 grams has been administered. The necrotic suppurative form of adenitis often clears up more quickly than the hard indurated nodules. The rapidity of improvement is claimed to be comparable with that of the arsenical treatment of syphilitic lesions; the authors raise the hope of an improvement in the gold treatment of pulmonary cases.

Ophthalmology

65 Nodular Corneal Opacities

E. L. GOAR (*Amer. Journ. Ophthalmol.*, February, 1931, p. 133), discussing nodular opacity of the cornea, remarks that this condition has been described under various names, and the clinical appearance as outlined by several authors does not always seem identical, yet all cases have certain common characteristics. The opacity usually appears in several members of a family, and it is slowly progressive over a period of years, with or without mild periods of irritation until vision is largely lost. The etiology is unknown. The lesions are bilateral and rather superficial, although in the later stages the deeper layers of the cornea may be involved. The affection consists in the appearance in the otherwise clear corneal tissue of numerous small rounded greyish non-confluent opacities, composed of a substance which is probably hyalin. The spots occupy principally the central portions of the cornea, and the larger nodules form clusters which cause the epithelium to bulge slightly; they seem to form gradually, and to remain unaltered for some years. Goar describes the case of a brick-mason who complained that his vision had been failing for about eighteen months; he had no other discomfort, but his eyes were sensitive to light, and watered. A sister and a brother were found to have similar trouble. On close examination with the loupe and lens it was noted that the superficial part of each cornea was covered with interlacing lines, and with tiny nodules arranged in groups and singly. The eyes were treated with dionin and hot applications, with no improvement. Six months later the irritation increased, and atropine, hot applications, and holocaine instillations were tried, the patient being given injections of diphtheria antitoxin. Six months later both corneas were densely infiltrated, and vascularization had begun from all sides. When the irritative stage gradually subsided it left both corneas opaque and densely vascularized. Weiner's wedge operation was performed, followed by radium applications, but no benefit was derived from it.

66 Comparison of Ophthalmic Ointments and Solutions

S. M. KIANG (*Nat. Med. Journ. of China*, February, 1931, p. 67) remarks that though the preparation of a well-mixed ophthalmic ointment is more difficult and its application less convenient than in the case of a solution, while the residue in the conjunctival sac blurs the vision, a greater amount of drug is nevertheless made available, and a more prolonged action is procurable, by the use of an ointment. Moreover, in certain skin conditions, and in diseases such as glaucoma, where a prolonged action is required, an ointment is preferable. The author conducted a series of experiments to contrast these two forms of medication. In comparing the length and strength of action, a solution was applied by a dropper to one eye, and the corresponding ointment by a graduated syringe in its fellow. The pupil of each eye was then measured at frequent intervals in strong daylight with the patient looking into the distance. In the case of 2 per cent. pilocarpine the action commenced earlier, and remained longer, in those eyes in which the ointment was used. With atropine 1 per cent. and homatropin 2 per cent. there was no difference in the rapidity of the action, but in the case of the ointment the maximum and total action lasted longer. The difference was not so noticeable as in the case of pilocarpine. Eserin in oil was more pronounced in action than when in watery solution, but did not differ appreciably from the ointment, though the latter was superior to the solution.

67 Glaucoma and Iritis

At the Brünner Ophthalmic Clinic between 1921 and 1929 there were treated 19 cases of iritis complicated by glaucoma. M. WOSTREY (*Bratislavské Lekarske Listy*, April, 1931, p. 361) reports that fourteen out of these cases were treated with subconjunctival injections of 0·2 to 0·3 c.cm. of adrenaline combined with a myotic (in ten cases), or with the instillation of a mydriatic (in four cases). The treatment was successful in ten cases. The combination of adrenaline with a mydriatic proved more successful in cases with predominance of iritis, whereas, when the glaucoma predominated, the combination with myotics proved more successful.

Obstetrics and Gynaecology

68 Acute Vulval Ulceration

L. M. PAUTRIER and J. ROTHERY (*Bull. Soc. Franç. de Dermat. et de Syph.*, April, 1931, p. 589) describe a vulval condition which they consider has received insufficient attention in France hitherto. Apparently it has been confused with herpes. There are three types. In the acute variety one or more ulcers appear on the labia majora or minora, accompanied by severe local pain and fever. The ulcers extend rather rapidly, are covered by a pseudo-diphtheral exudate, and have an offensive odour. Healing occurs in approximately fifteen days. A subacute type runs a slower, afebrile course, and is subject to repeated relapses. In the third form there are miliary multiple ulcers as large as pins' heads, surrounded by an inflammatory zone. The authors add a fourth type—a single rounded ulcer resembling a syphilitic chancre. They report the case of a patient who was six months pregnant when an ulcer appeared; it was elliptical, grew to the size of a sixpenny bit, and was situated on the inner surface of the right labium majus. It was slightly raised, with ill-defined edges and a slightly infiltrated base. The inguinal glands were not enlarged. All tests for syphilis gave negative results, but smears and cultures showed abundant growths of *B. crassus*. The ulcer healed rapidly under local antiseptic treatment. L. M. PAUTRIER and R. GLASSER (*ibid.*, p. 593) describe another case. A woman, aged 24, was admitted four days after coitus, complaining of burning pains and much discomfort, followed by painful bilateral ulceration of the labia majora; the discharge was most offensive. There was considerable oedema, but no lymphadenitis. Local treatment consisting of sitz baths and the application of permanganate lotion healed the ulcers in a week. All the syphilitic serum tests were negative, and *B. crassus* was not found. The authors term this condition "gangrenous ulcer," and suggest that it is analogous to ulcerative and gangrenous balanitis.

69 Pernicious Vomiting of Pregnancy

J. VORON and H. PIGNARD (*Gynécol. et Obstét.*, April, 1931, p. 289) have found the coefficient of Maillard, as modified by Lanzenberg, of great diagnostic and prognostic value in the pernicious vomiting of pregnancy. This modified coefficient is obtained by dividing the sum of the urea, ammonium, and amino-acid nitrogen figures by the sum of the two latter. It was described by its author as the coefficient of ureogenic imperfection, and this is due to the fact that in this condition hepatic insufficiency is constantly present. Towards the end of the fourth month of a normal pregnancy the coefficient remains at the normal figure of 6.58; it rises to 11.32 at the end of the eighth month, and then drops progressively to 7.5 at term. A rise to between 15 and 25 indicates a condition of average severity, which can be cured by correct medical measures. Should the rise be above 25,

a particularly grave type is present, and therapeutic abortion must be considered. Should the coefficient be below 15, cure can be rapidly obtained by simple measures, despite the apparent severity of the clinical signs. The coefficient can also be employed to differentiate cases of simple or nervous from pernicious vomiting. Eight cases illustrating these points are recorded.

70 Sex Hormone and Endothelial Permeability

According to L. BICKEL (*Zentralbl. f. Gynäk.*, April 4th, 1931, p. 1250), endothelial permeability, as estimated by the number of capillary ecchymoses following temporary ante-cubital compression, is relatively small in pregnancy, and comparatively great in the climacteric ; its increase during the latter constitutes a valuable objective sign of the menopause. Oral administration of the ovarian hormone led in the majority of cases to diminution or cessation of the haemorrhages following pressure. From these findings it is inferred that endothelial permeability varies inversely with the blood content of the sex hormone ; but the value of this test is lessened by the fact that permeability is subject to spontaneous variation in the same patient, is affected by nephritis and diabetes, and is diminished by sedative drugs such as the bromides and luminal. It is probable that the sex hormone, in diminishing endothelial permeability, does so in part by inducing hypercholesterinaemia ; oral administration of cholesterin has the same effect.

Pathology

71 The Blood Pressure in Cerebral Embolism

Cerebral embolism causes in normal animals an initial fall in arterial pressure with slowing of the cardiac contractions ; a more or less prolonged hypertension supervenes, accompanied by an increase in the differential pressure, and an exaggeration in the volume of the cardiac contractions. M. VILLARET, L. JUSTIN-BESANÇON, and S. DE SÈZE (*C. R. Soc. de Biologie*, May 22nd, 1931, p. 231) record experiments on dogs which show the influence on these cardio-vascular effects of cerebral embolism of vagotomy in the neck and injections of adrenaline. The results indicated that these two procedures suppressed the initial hypertension and bradycardia caused by the embolism ; this suppression abolished equally the rise in the differential pressure and in the volume of the cardiac contractions. The increased importance and duration of the post-embolic hypertension suggests that this paroxysmal hypertension is normally limited or checked by a depressive reaction of pneumogastric origin.

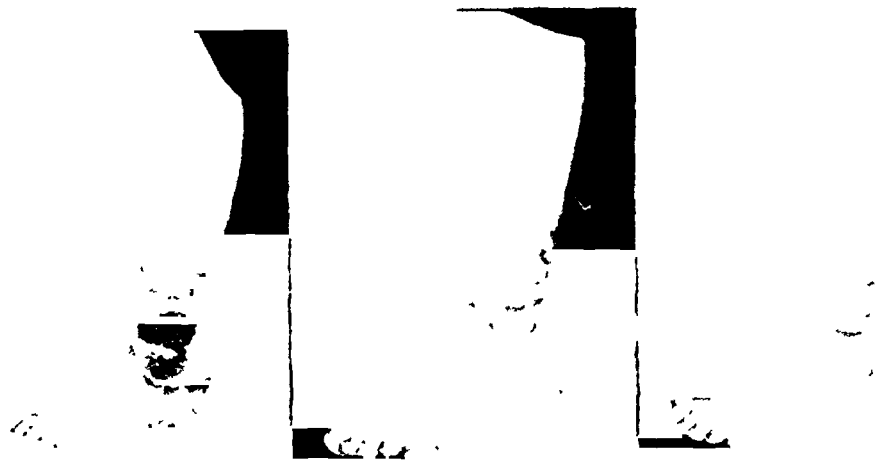
72 Effect of Opium on the Blood Sugar of Non-diabetics

R. N. CHOPRA and J. P. BOSE (*Ind. Journ. Med. Research*, April, 1931, p. 1087), who previously discussed the effects of opium on the blood sugar in diabetes (see *Epitome*, 1930, vol. ii, para. 424), now record observations on the effect of opium upon the blood sugar of normal persons suffering from no disturbance of carbohydrate metabolism. Any possible psychic effect was eliminated by concealing the taste and smell of the drug with oil of citronella, so that the patient was ignorant of its nature. It was administered in a mixture containing 1 grain of opium to the ounce. Commencing with 1 or 2 grains daily, the dose was increased to 14 grains without discomfort, and in some instances it was gradually reduced, or suddenly stopped, without producing any symptoms. Most of the patients left hospital under the impression that they had been receiving an excellent general tonic. Notes of twelve cases are given, with records of the urinary output, blood sugar content, body weight, and dosage over a period varying from 12 to 23 days. There was a sense of general well-being on discharge, and one man, admitted for epigastric pain, lost all his symptoms and regained his appetite. An increase in the total urinary output was noted, except in four cases in which it was unchanged. The blood sugar level remained constant in most, but one case in which it was abnormally low on admission was much benefited, the blood sugar increasing and the weakness improving.

73 The Blood Urea in Diabetic Coma

According to M. LABBÉ and R. BOULIN (*Ann. de Méd.*, April, 1931, p. 386), in approximately half the cases, diabetic coma is accompanied by a moderate azotaemia (the amount of urea remaining at about 1 gram), and by a diminished excretion of urea, albuminuria, and the appearance of renal casts. The other classical characters of diabetes, including the state of the alkaline reserve, glycaemia, and glycosuria, are not altered. The urinary chlorides are markedly lowered, and those of the blood may be slightly diminished. The urinary acétone bodies are a little increased ; they are never totally absent. The azotaemia and passage of the acetone bodies are due to degenerative lesions of the convoluted tubules. Commencing as it does during the first hours of coma, this retention of urea is of great prognostic value ; cases with this complication end fatally twice as often as those without it. The absence of diminution in the azotaemia on the second day of the coma is an ominous indication. Death in these cases may be due to an intractable acidoketosis, to cardiac collapse, or to an intoxication of unknown nature distinct from acidoketosis. Notes on five cases are given, and the literature on the subject is reviewed.

74 The Schultz-Charlton Reaction in Relapses of Scarlet Fever



W. LOOK (*Arch. f. Kinderheilk.*, March 13th, 1931, p. 65) records 14 cases of relapse in scarlet fever among patients, aged from 4 to 26 years, in whom the relapses occurred between the seventeenth and forty-seventh days. The Schultz-Charlton reaction was positive in 13 cases ; in 5 cases it was positive both in the primary attack and in the relapse ; in 1 case the reaction was doubtful ; and in the remaining 8 the rash of the primary attack had disappeared or the test was not performed. The Schultz-Charlton reaction, therefore, in the relapse of scarlet fever does not differ from that in the primary attack. When it is not obtainable on the first or second day of the eruption, the test should be repeated on the second or third.

75 Etiology of Post-vaccinal Encephalitis

H. M. WOODCOCK (*Journ. Royal Army Med. Corps*, April, 1931, p. 275), recalling the statement of S. Smith that only since the introduction of vaccine prepared by passage through rabbits has any considerable series of cases of encephalitis or encephalomyelitis occurred, suggests that in various parts of Europe and America rabbits and other rodents such as mice are very liable to a naturally occurring encephalitis or encephalomyelitis, characterized by marked perivascular infiltration and the occurrence of the "encephalitozoon" bodies. In a summary of the work of various authorities on this condition, that of Cameron and Maitland is especially noted. These workers, after inoculating rabbits from an acute case of human encephalitis, found the encephalitozoon bodies, first in a rabbit of the third passage, and subsequently in all the animals. They consider that the bodies occurred as a spontaneous infection in the first rabbit and were then transmitted. Woodcock believes that the production of the bodies was more likely due to the inoculated human virus, and concludes that rabbit encephalitis may be induced by several causes, including human encephalitic virus. A brief comparison is made between the encephalitozoon, the Negri body, and the Guarnieri bodies of small-pox and vaccinia ; the histological changes caused by each are discussed. From all these facts, Woodcock suggests that rabbit encephalitis can be transmitted to man, and that with repeated passages a dangerous factor is added, as the ferment virus of the vaccine, originally dermotropic, will tend to have increasingly added a neurotropic quality.

THE CROWNING ACHIEVEMENT

U.G.B. MEDICAL BOTTLE *Service*

DURING the past ten years at tremendous expense, a very wide range of automatic machine mould equipment has been built up by the U.G.B. to cater for practically every bottle requirement of the Chemist and Dispenser. New and attractive shapes are now being added from time to time.

The Crowning Achievement was the introduction of the "Washed and Sterilised Ready-to-Use Package" which is daily growing in demand.

Only a small percentage of the actual cost of this service is passed on to the customer.

Supplied either for corks or complete with Rustless White Enamelled Screw Caps.

Once you have experienced the value and convenience of this U.G.B. Service you will use nothing else. Try it NOW and be prepared for the WINTER.

Obtainable from all leading Wholesalers.

"VARIBAN"

Elastic Plaster BANDAGE

MADE from a specially woven selvedge material, possessing very elastic properties, evenly spread with an Antiseptic Zinc Oxide Paste. Self-adhesive, readily conforming to the shape of the limb, and when carefully applied forms an even surface dressing which will not crease or slip. Firm support. Easy to remove. Extensively used in many well-known hospitals for the treatment of VARICOSE ULCERS, VARICOSE VEINS, SURGICAL and ORTHOPAEDIC CASES, etc. Their application for treatment of Varicose Ulcers, etc., does not necessitate the patient lying-up; in fact, permits the continuance of light duties. Ensures rapid healing.

SUPPLIED in WIDTHS

2"	2½"	3"
1/7	1/9	2/- EACH

When stretched measure six yards (approximately).

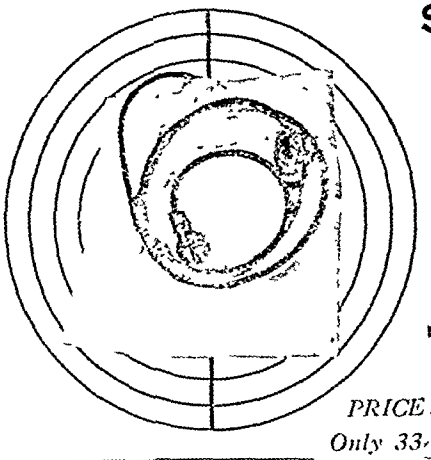
SAMPLE 3 in. "VARIBAN" ELASTIC PLASTER BANDAGE sent POST FREE on receipt of P.O. for 2/3.

"CELLANBAND"

PASTE BANDAGES

in the Treatment of VARICOSE ULCERATION, PHLEBITIS, etc.

MESSRS. CUXSON, GERRARD & CO. Ltd. have pleasure in informing the members of the medical profession that they are now manufacturing Paste Bandages—under the descriptive name of "Cellanband"—strictly according to the formula mentioned in the article quoted below.



"The paste-bandage constitutes a definite improvement upon the methods so far available, both in convenience of application and in the results obtained."
(Vide article on page 560, "B.M.J.," Oct. 4th, 1930.)

STEADY CONTINUOUS WARMTH APPLIED LOCALLY

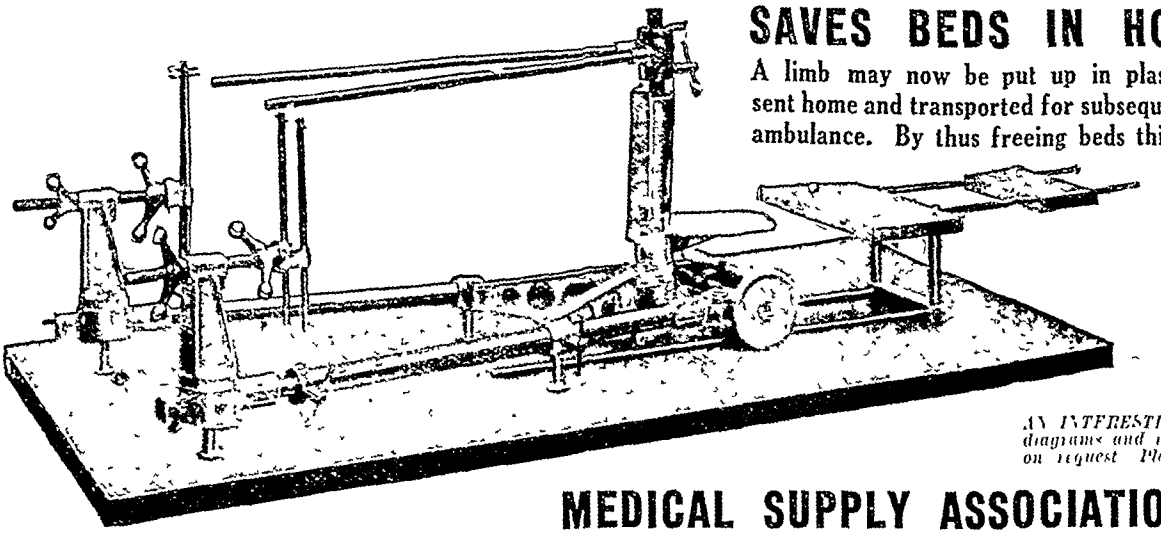
To Relieve Rheumatic Pains, Chills, etc., and all such Ailments.

The THERMEGA ELECTRIC PAD takes the place of a hot water bottle in all cases where the local application of heat is prescribed. The heat obtained is instantaneous, constant, and easily regulated as desired. The THERMEGA pad, no larger than an ordinary hot water bottle, is handy and practical for use while travelling. It can be used from any lamp-socket or wall plug at any voltage (100-250). The average cost of current is only 1d. an hour (at 6d. a unit). A special Thermostat control maintains a level temperature and makes overheating impossible. Ask for demonstration and particulars. Sold by all the big stores, chemists, and electrical dealers, or direct from

THERMEGA LIMITED

53, VICTORIA STREET, LONDON, S.W.1.

PRICE: *Only 33/-*



An IMPROVED and MODIFIED

Portable Traction Apparatus

An exceedingly efficient and convenient apparatus for putting up in plaster the lower limbs or trunk; also when applying bone plates or Parham and Martin's Bands to long bones of the lower extremity. Provides the more essential movements of expensive and bulky Orthopaedic tables at a fraction of the cost.

Quickly adaptable for the following positions:

Extension of whole lower limbs
Movements about hip-joint:
Abduction to any degree—
Hyperextension—Flexion—
Internal and External Rotation.
Flexion of knee-joint.
Inversion and Eversion of foot.

SAVES BEDS IN HOSPITALS

A limb may now be put up in plaster, the patient sent home and transported for subsequent treatment by ambulance. By thus freeing beds this new apparatus saves its cost many times over.

Folds compactly for storage or transit in plywood case 35 in × 15 in × 11 in

BANTAM Coffee

Bantam Coffee is prepared from the finest selected Empire grown beans which are powdered and at the same time extracted so that it requires instantly and completely when hot water or milk is added. A little Bantam Coffee dropped in a glass of warm milk makes a very palatable beverage. Bantam Coffee is absolutely free from adulterants and has been awarded the certificate of the Institute of Hygiene.

A 2/- tin yields 50 cups of delicious coffee.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or who wish to prevent recurrent attacks of mental trouble, temporary patients; and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

HAYDOCK LODGE,
NEWTON-LE-WILLOWS, LANCASHIRE.

President: LORD WAKEFIELD OF HYTHE, C.B.E., LL.D.
Treasurer: SIR LIONEL FAUDEL-PHILLIPS, Bart.
Physician-Supt.: J. G. PORTER-PHILLIPS, M.D., F.R.C.P.

This Registered Hospital is now situated at Monks Orchard, in some 250 acres of park, pleasure, and farm grounds.
Applications can be considered on behalf of patients of the educated classes in a presumably curable condition.
With a view to early treatment voluntary or uncertified patients are admitted.
Patients who can contribute 5 guineas weekly towards the cost of treatment and maintenance may be received as vacancies arise. The Committee will also consider applications for admission at lower rates, and in certain cases will be prepared to admit patients free of charge.
Every facility for specialized investigation and treatment is provided in the Lord Wakefield Science and Treatment Unit. In this Unit is found the X-ray and Dental Departments and the Bio-Chemical, Pathological, and Psychological Laboratories.
Furthermore, provision is made for Electro-Therapy and Hydro-Therapy to be carried out in all their forms.
In addition to the Resident Medical Staff, Consultants in special branches of Medicine and Surgery are available whenever required.
The comfort of sensitive patients is greatly enhanced by the fact that the majority are given single bedrooms.
For forms and further particulars apply to the Physician-Superintendent at the Hospital.

Burgh of Kilmarnock.

ASSISTANT MEDICAL OFFICER OF HEALTH.

The Town Council invite applications from duly qualified and registered Medical Practitioners holding the Diploma in Public Health, or an equivalent qualification, for the appointment of Assistant Medical Officer of Health for the Burgh. Candidates must not exceed 35 years of age.

The person appointed will be required to carry out all the duties assigned to him by the Medical Officer of Health, under whose direction and supervision he will act. He will be required to devote the whole of his time to the duties of the office and to reside in the Burgh. He will not be allowed to engage in private practice.

Some experience in Public Health work, including School Medical Inspection is desirable.

The inclusive annual salary is £500, rising by annual increments of £25 to £675, subject to the satisfactory performance of duties. The successful candidate will be required to pass a medical examination.

Applications (enclosed in envelopes endorsed "Assistant Medical Officer of Health"), stating age, qualifications, previous experience and present employment, together with one copy of recent testimonials, should be lodged with the Subscriber by July 22nd.

Council Chambers, Kilmarnock. July 9th, 1931. N. J. CAMPBELL, Town Clerk.

Birmingham Public Health DEPARTMENT.

TUBERCULOSIS SECTION.

Applications are invited from single male Medical Practitioners for the post of ASSISTANT MEDICAL OFFICER in the Tuberculosis Section of the Public Health Department. The successful candidate will be employed both in a Sanatorium and a Dispensary.

Candidates should have held a resident General Hospital appointment, or an appointment in some Institution set apart for the treatment of those suffering from Tuberculosis.

The salary will be at the rate of £400 per annum, rising by annual increments of £25 to £450 per annum, with emoluments valued at £150 per annum.

The officer appointed will be required to refund to the Council all fees, allowances, and emoluments (other than the foregoing) received by him.

The appointment will be subject to the Birmingham Corporation's Superannuation Scheme, and to the candidate passing a medical examination, and will be subject to one month's notice on either side.

Forms of application may be obtained from, and should be returned with three recent testimonials to, the Chief Clinical Tuberculosis Officer, 44a, Broad Street, Birmingham, by 9 o'clock on July 24th.

Council House, Birmingham. F. H. C. WILTSHIRE, Town Clerk.

City of Portsmouth.

SECOND ASSISTANT RESIDENT MEDICAL OFFICER.

Applications are invited for the appointment of a Second Assistant Resident Medical Officer for the Saint Mary's Hospital, St Mary's Institution and Children's Home. The appointment will be limited to a term not exceeding one year, and will be subject to one month's notice on either side. Salary at the rate of £300 per annum, with furnished apartments, rations and other allowances. Candidates must be single gentlemen, and duly registered. Preference will be given to those having a knowledge of the treatment of mental diseases, and who have experience in surgical work. A Resident Medical Superintendent is in attendance. Applications on printed forms, to be obtained from me or at the Public Assistance Offices, 1, St Michael's Road, Portsmouth, accompanied by not more than three recent testimonials, and a description of the diplomas, certificates of degrees, licences, and other instruments held by the candidates, must be returned to me, endorsed "Second Assistant Resident Medical Officer," by Tuesday, July 28th.

The Guildhall, Portsmouth. July 14th, 1931. F. J. SPARKS, Town Clerk.

Hertford County Hospital.

Applications are invited for the post of HOUSE PHYSICIAN (male). Salary £150 per annum, with board, residence, and laundry. The appointment is for six months in the first instance.

Applications, with copies of three recent testimonials, should be sent to the undersigned. PERCY G. BROWN, General [illegible] Terms to [illegible]

County Borough of Tynemouth.

ASSISTANT MEDICAL OFFICER (Non-Resident).

The Council of the County Borough of Tynemouth invite applications for the appointment, for a period of one year, of an Assistant Medical Officer for the Poor Law Institution, Preston Road, North Shields, and the Children's Homes.

Salary £300 per annum, inclusive of vaccination and all other fees. The officer appointed will be required to pay to the Council all fees received by him for inquests, certifying lunatics, etc., to devote the whole of his time to the duties of the office (which includes the training of Probationer Nurses), to reside in close proximity to the Institution, and to act under the direction of the Medical Officer.

Applicants must be duly registered under the Medical Acts, and be qualified by law to practise in Medicine and Surgery in England and Wales, and the candidate appointed will be required to produce his licences, diplomas, or certificates to the Council.

Applications must be made on a printed form which may be obtained from the Public Assistance Officer, 4, Northumberland Square, North Shields, on receipt of a stamped addressed foolscap envelope, and must be returned to me accompanied by copies of testimonials as to professional ability and personal character, by first post on July 28th.

Canvassing, either directly or indirectly, will be a disqualification.

Town Clerk's Office, Tynemouth. July 10th, 1931. C. C. HENDERSON, Town Clerk.

Essex County Council.

FIRST ASSISTANT MEDICAL OFFICER.

The County Council of the Administrative County of Essex invite applications for the above post from registered Medical Practitioners holding a Diploma of Public Health, with experience in Maternity and Child Welfare and Gynaecological work, and not over 45 years of age.

The commencing salary attached to the appointment will be at the rate of £750 to £800 per annum, according to experience, and will rise, subject to satisfactory service, by annual increments of £25 to £900 per annum. Travelling expenses will be paid by the Council.

The Local Government and Other Officers Superannuation Act, 1922, has been adopted by the County Council.

Applications on the prescribed form, obtainable from the undersigned, and accompanied by copies of not more than three testimonials, which will not be returned, should be addressed to me and delivered at the Shire Hall, Chelmsford, not later than 10 a.m. on Wednesday, July 22nd.

Shire Hall, Chelmsford. July 8th, 1931. JOHN H. GOOLD, Clerk of the County Council.

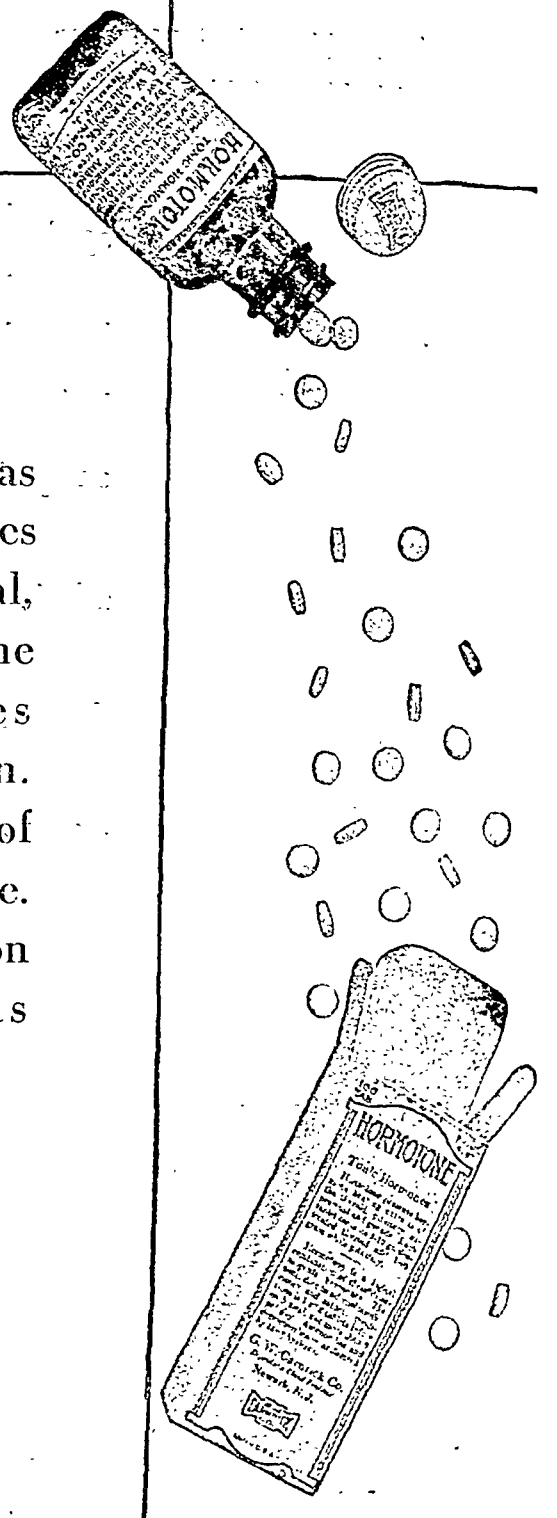
WHETHER THE PATIENT IS

aged  and feeble  or so young  that his digestive system works less energetically than his limbs  or is an adult business man  healthy but deskbound  —prescribe AGAROL with confidence for the relief of constipation and to aid in restoring regular bowel function.

AGAROL Brand Compound is the original mineral oil and agar-agar emulsion with phenolphthalein. It softens the intestinal contents and gently stimulates peristalsis.



Gentle enough for little patients; active enough for the chronic state of the adult and aged patient.

A supply gladly sent for trial.

CAUTION IN THE USE OF APERIENTS

The dangers attending the use of irritating and drastic purgatives are being increasingly realised Over and beyond the injury that may result from violent intestinal action in acute abdominal conditions, the pain and discomfort of many chronic conditions are much increased by the employment of laxative drugs which irritate the large bowel.

It is a great virtue of Eno's "Fruit Salt" that it causes no irritation in the large intestine. It can, therefore, be safely and usefully employed in dysentery and colitis, as well as in inoperable partial colonic stenosis. Eno's "Fruit Salt" has, also, often been found of great value when taken regularly in those non-acute colonic and pericolonic conditions —kinks, adhesions, etc.—which, although not calling for operative treatment, yet give rise to a great deal of so-called "appendicular" pain.

The ENO "Medical Reminders." The Proprietors of ENO'S "Fruit Salt" will appreciate the opportunity of sending, free of charge, to any member of the Medical Profession a copy of any of the following —

"The Doctor's Pocket Remembrancer"
"The Practitioner's Pocket Book"
"The Panel Doctor's Pocket Book"
"The Doctor's Emergency Reminder"
"Urgent Abdominal Diagnostics"

[REGISTERED AS A NEWSPAPER

Valentine's Meat-Juice

In Typhoid Fever, Diarrhoea and Cholera Infantum, when it is Essential to Sustain the patient without irritating the Digestive Organs, the Ease of Assimilation and Power of Valentine's Meat-Juice to Restore and Strengthen has been demonstrated in Hospital and Private Practice.

THE quickness and power with which VALENTINE'S MEAT-JUICE acts, the manner in which it adapts itself to and quiets the irritable stomach, its agreeable taste, ease of administration and entire assimilation recommend it to physician and patient.

Physicians are invited to send for brochures containing clinical reports.

Side view of Cup The Cup flange and circular pad are made as one moulding

SALT'S COLOSTOMY BELT

with sterilizable Rubber Cup
(Registered Pat No 749046)

EMBODIES THESE VITAL POINTS

- Detachable Cup sterilizable by boiling repeatedly without deterioration.
- No crevices or metal fittings to hold faeces.
- Smell reduced to a minimum.
- Minimum of bulk.
- Cups easily and economically replaced.

This belt is designed for cases where faeces are of a solid nature or the amount is small

The special feature is the cup, which is made of moulded rubber in one piece, having no corners or crevices, and therefore does not retain the odour.

TO COUNTER ACIDOSIS

As SALVITAE contains 59% of Potassii et Sodii Citro Tartras and 30% of Sodii Sulphas it is of great value both in maintaining health and in the treatment of disease, through eliminating deleterious nitrogenous products and favourably influencing circulation, glandular secretions, peristalsis, and metabolism

The fruit acids of SALVITAE are converted in the system into potentially basic alkaline carbonates, thus enabling the blood to keep the uric acid compounds in solution, and facilitate their removal.

OVALTINE

WHEN SLEEP IS DIFFICULT

Judged by the numerous reports received from physicians and also from grateful patients, the use of "Ovaltine" for ensuring sound refreshing sleep deserves the widest recommendation.

It has been remarked that a more helpful prescription could not be wished for because:

1. Taken last thing at night before retiring it exercises a pronounced sedative effect and one that is natural in every sense.
2. It has a pleasantly soothing action on the stomach and nervous system, and does not cause the slightest digestive unrest, or occasion constipation.
3. It promotes a sufficiency of healthful sleep without resourse to hypnotic drugs..

"Ovaltine" is a delicious concentrated extraction of malt, milk, and eggs, in the form of golden granules, which dissolve instantly in milk.

A liberal supply for clinical trial sent free on request.

Local Anæsthesia in Surgical Practice

UNUNITED FRACTURE.

Typical Case.

H C A, aged 27 years.

Diagnosis: Ununited fracture of the right radius and ulna at the mid-point.

Operation: Intramedullary autotransplant.

Anaesthesia: Brachial block, 10 c c of 2 per cent. Novocain-Adrenaline solution, local infiltration for removal of graft.

Operation: The patient was given 1/4 grain morphine and 1/100 scopolamine at 9 a m. At 10 a m the operation was performed. Brachial anaesthesia was established with the patient sitting in a chair, 10 c c of 2 per cent Novocain-Adrenaline being used A large rhomboid infiltration was then made on the anterior surface of the leg. The site of the fracture was then reached by two incisions, and the ends of the bones freshened With a large drill the narrow cavity was reamed out and dowels were prepared from bone removed from the tibia These dowels were fitted into place, the wound sutured, and the patient made an uneventful recovery The anaesthesia for the removal of the transplant was obtained by a subdermal infiltration of the leg, and in addition the needle was carried down to the periosteum, making an infiltration along the line of the transplant to be removed —EXTRACT from PRACTICAL LOCAL ANAESTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anaesthesia will be found in the above work, published by Henry Kimpton, 263, High Holborn, London, W C 1)

THE SAFEST LOCAL ANAESTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify "Novocain" for your next operation.

Does not contain Cocaine, and does not come under the Dangerous Drugs Act.

66 **Eucortone** 99

(Cortical Extract of Suprarenal)

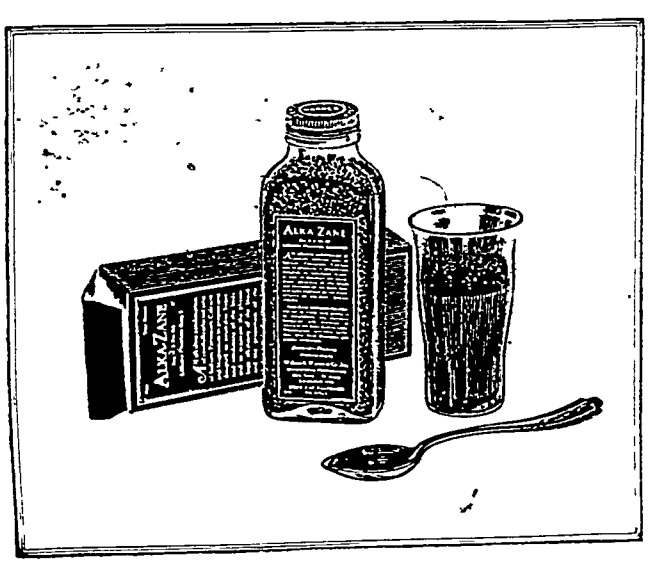
In the treatment of

Addison's Disease

Efficacy established by biological tests and clinical use

(*Journal of Physiology*, June 6, 1931: *Proc. Physiol. Soc.* May 2, pp. 4, 5, and 9)

"Eucortone" is prepared by the method of Swingle and Pfiffner, and is highly successful in the treatment of Addison's Disease. Particularly striking is the rapid restoration of appetite, weight, strength, and feeling of well-being. Biological tests and clinical use show that "Eucortone" contains the long-sought cortical hormone in an active state and is free from adrenalin activity. The extract contains no irritant or toxic substance, and is sterile.



1 c.cm. is equivalent to 30 grams of cortex. In rubber capped bottles of 25 c.cm.

Proverbs Up-to-date No 2

PREVENTION IS BETTER THAN CURE

An excellent maxim—and one that holds good for such conditions as *are* easily curable. Unfortunately Dental Caries is not, so that *Prevention* is the only really satisfactory method of combating this affection.

In this connection, it must be remembered that the Dentist is a surgeon, who is called upon, more often than not, to remove diseased and useless tissues; which are replaced by appropriate artificial substitutes. It is in the mission of preservation and prevention that Gibbs co-operate with the Dentist.

"Visit your Dentist twice a year, and use Gibbs Dentifrice twice a day" is a phrase reiterated in Gibbs nation-wide advertising. The vital function of the Dentist in the plan of preventive dentistry is never left in doubt; and the twice daily use of Gibbs Dentifrice is urged as the best way to consolidate his good work. Gibbs Dentifrice has for many years won the approval of leading Medical Authorities. It provides a cleansing agent which removes all harmful deposits — quickly and surely — whilst bringing out the natural beauty of the teeth by safe polishing.

GIBBS MOUTHWASH

A Peroxide Mouth Wash in Powder form. A new Preperation by Gibbs that has met with instant success.
Gibbs Mouth Wash produces Oxygen in the mouth, which has a wonderfully efficient cleansing and antiseptic effect; and definitely purifies the breath.
Although intended for twice daily household use, Gibbs Mouth Wash provides an excellent and safe mouth wash for use following extractions.

"THESE RESULTS ARE OF FAR-REACHING IMPORTANCE AND OPEN UP A WIDE FIELD FOR THE EMPLOYMENT OF DIMOL IN COLONIC IRRIGATION."

Vide The British Journal of Physical Medicine, May, 1931, pp. 32 33.

"Colonic irrigation was administered to two separate patients, ONE being treated with *Dimol Lavage Powder in the douche.*

The OTHER (the control) being treated with a slightly hypotonic saline solution only."

The results were as follows:—

	With Dimol Solution.		*Without Dimol Solution.*	
Specimen	*Bacteria per c.c.*	*B. coli per c.c.*	*Bacteria per c.c.*	*B. coli per c.c.*
15 minutes	*5*	*0*	*More than 2,000*	*50*
20 ,,	*3*	*0*	*do.*	*More than 2,000*
30 ,,	*2*	*0*	*do.*	*1,000*

The addition of Dimol Lavage Powder to the fluid injected provides a highly potent bactericide for the purpose of destroying any micro-organisms not removed by the mere mechanical action of the wash and is "**an outstanding advance in Colonic Therapy.**" *A full reprint of the article which appeared in the "Journal of Physical Medicine" will be sent on application.*

DIMOL LABORATORIES, LIMITED, 40, LUDGATE HILL, LONDON, E.C.4

COD-LIVER OIL in its most palatable and easily assimilated form is the CREAM prepared by Thomson of Elgin.

It is readily acceptable to children and adults.

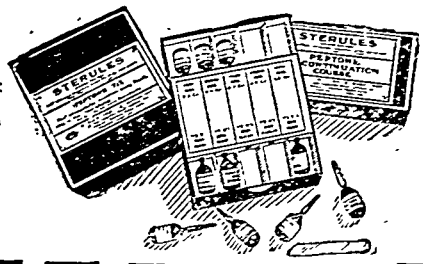
Free from the difficulties of taking, usually associated with Cod-Liver Oil preparations.

Contains 50% recently refined Cod-Liver Oil of high vitamin content.

Maximum vitamin efficiency ensured by freshness of preparation every week.

Fresh eggs used in the making enhance nutrient value.

The Lancet, January 4th, 1930, says: "We can recommend this preparation."



Bottles 4/-, 7/-, and 10/-, post free by return.

Telegraphic Address: "MARTINDALE, CHEMIST, LONDON." Telephone: LANGHAM 2441.

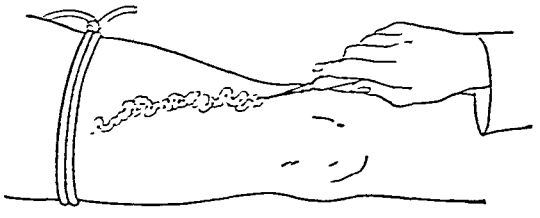
TRADE MARK

A NEW PREPARATION

COLLOSOL CALCIUM
WITH
VITAMIN D
ORAL

THIS new Collosol preparation containing 1% (approx.) of a colloidal calcium salt of the fatty acids of cod liver oil is standardised to contain 250 M.R.C. units per teaspoonful of Vitamin D, in the form of irradiated Ergosterol (Pat. 236197/24) equivalent in Vitamin D to half a teaspoonful of the finest cod liver oil.

Modern biochemical science has shown that utilisation of calcium, when absorbed from the intestinal tract is largely a function of Vitamin D. Normally this accessory food factor is present in a well balanced diet, and is present in some natural oils. It is to this factor that cod liver oil owes its antirachitic properties.



Rats fed on a deficiency diet inducing rickets can be cured in a few days by the administration of Collosol Calcium with Vitamin D. Rachitic rats when *injected* with Vitamin D are practically unaffected whilst controls given the same doses *orally* are rapidly cured. It should be noted that the oral route is the natural method for administering vitamins.

SEAL OF CHARLEMAGNE.—Charlemagne's long reign of forty-six years was devoted to re-moulding the world after the ruin and desolation which followed the break-up of the Roman Empire. His greatness as a warrior was even surpassed by his power as an administrator. A contemporary writer describes him thus: "His body was large and strong; his stature tall but not ungainly, for the measure of his height was seven times the length of his own feet. The top of his head was round; his eyes were very large and piercing. His nose was rather larger than is usual; he had beautiful white hair and his expression was brisk and cheerful; his appearance was dignified and impressive. He had good health, but for four years before his death was frequently attacked by fevers, and at last was lame of one foot. Even then he followed his own opinion rather than the advice of his doctors, whom he almost hated, because they advised him to give up the roast meat to which he was accustomed, and eat boiled instead. He took delight in the vapour of naturally hot waters, and constantly practised swimming, in which he was so proficient that no one could be fairly regarded as his superior."

"I-so-gel" Granules

Indicated in Chronic Constipation, Colitis, and allied intestinal disorders

"I-so-gel" is a natural vegetable material. The granules absorb many times their volume of water and swell into a gelatinous mass which both stimulates natural intestinal movements and soothes inflamed intestinal mucous membrane. Indicated in chronic constipation, colitis, and allied intestinal disorders. Action purely mechanical. Sugar-free. Ideal for diabetics.

In bottles at 2/6 and 4/6 each

Descriptive literature sent post free on application.

Allen & Hanburys Ltd., London, E.2

Telephone: 3201 Bishopsgate (10 lines). Telegrams: "Greenburys Beth London."

A Non-Griping and Palatable Preparation of Senna

Contain "Lixen" in a fruit basis.

Really pleasant to take.

Appeal particularly to children.

Each lozenge is equivalent to 6 large senna pods.

In boxes of 12 and 24 lozenges for prescribing. In bottles of 100 lozenges for dispensing.

Descriptive literature and clinical trial sample will be sent on request.

NINETY-NINTH ANNUAL MEETING, EASTBOURNE, 1931

President's Address

ON

PUBLIC HEALTH—TO-DAY AND TO-MORROW

BY

W. G. WILLOUGHBY, M.D.LOND., D.P.H.CAMB.
MEDICAL OFFICER OF HEALTH, EASTBOURNE

I find it difficult to express how very much I appreciate the honour of my election to the Presidency of the British Medical Association. I recognize that, in addition to the honour, it involves a great responsibility in that I have to follow such a long roll of distinguished predecessors. I can only thank you most sincerely, and try to deserve the trust you have so kindly placed in me.

It has been pointed out as noteworthy that this is the first occasion on which a full-time medical officer of health has held this position, and on behalf of medical officers of health, as well as personally, I much appreciate this aspect of the honour I have received. Such an event, however, only illustrates the catholicity of the Association, and its endeavours to promote the co-ordination of every variety of medical practice in the interest both of the public and of our profession.

I think that too much stress should not be laid on the circumstance that a medical officer of health holds this position for the first time. It tends to obscure the very important fact that preventive medicine has formed from time immemorial an important part of the work of every branch of the profession. The same thing obtains now and will undoubtedly continue in the future to an even greater degree.

The existence of the medical officer of health and of the public health service is due to a very great extent to the fact that at all times members of the profession have observed and recorded the direct and contributory causes of disease, and have studied how disease generally, and diseases in particular, can be prevented. The Ministry of Health and medical officers of health are systematically applying and extending the results of these observations and records.

There is evidence that as long ago as the time of Hippocrates the circumstances of disease were observed and recorded. Not only are the brilliant discoveries of medical men of the past, and particularly since the eighteenth century, increasingly applied for the benefit of the public, but the less spectacular, though equally important, work of what one may term the rank and file of the profession has been also most important in contributing to the improved conditions of health of the present day. As regards our Association itself, I may remind you that Sir Charles Hastings, our founder and president ninety-nine years ago, was himself a lecturer on sanitary science. The office of medical officer of health is, in fact, one of the developments of the progress rendered possible by the general advance in the science of medicine.

It is natural that as a medical officer of health I should address you to-day on matters connected with public health, and I propose, after a brief reference to its improvement in recent years, to comment on its present position and on some factors that will affect the prospects of its improvement in the future. It would be tempting to dwell at some length on the achievements of the past, due so largely to the observant work of our predecessors, and its subsequent adaptation, extension, and application by highly organized methods, but a consideration of the present and of the possibilities of the future is my aim this afternoon.

RECENT IMPROVEMENTS IN PUBLIC HEALTH

As regards the past, I will only briefly remind you of such evidence of progress as the increase in the expectation of duration of life, the decrease in the general death rate and in the infant mortality rate, the disappearance or lessened occurrence of some diseases, the mitigation of the severity of many others, the wholesale advance in the skill, technique, and safety of surgery, and the improved provision for the care and prevention of sickness.

The increase in the average duration of life has been very considerable in the present century, averaging more than twelve years. Although this is owing mainly to the decrease in infant mortality, it is also partly due to the general lowering of death rates at other ages. A comparison of the three official life tables for England and Wales representing the conditions existing in 1906, 1911, and 1921 respectively, shows an increase of average expectation of life at all ages, especially in infancy, where the chances of survival increased by about 40 per cent. in the fifteen years. Ten per cent. more of the population now reach the age of 50. The annual death rates for England and Wales averaged nearly 20 per 1,000 in the last decade of the nineteenth century, and now average about 12 per 1,000. The infant mortality rates averaged 167 per 1,000 births in the last decade of the nineteenth century; during the last ten years they have averaged 74, and in 1930 the rate was 60 per 1,000 births. These and similar facts indicate the great advance that has been made in public health, especially in this century. The most casual observation shows the great improvement that has occurred. In spite of abundant evidence of progress, however, it is not possible to be satisfied with the position of the general health to-day.

PUBLIC HEALTH TO-DAY

The medical officer of health regularly receives from the registrar of births and deaths copies of all certificates of deaths, and also receives notifications of certain illnesses—so far a definite and generally accurate summary of those events in his district. He knows the extent to which ailments are affecting elementary and some other school children, and persons who attend certain clinics. He also has less definite, but abundant information as to other illnesses that are occurring in his district. It is his duty

to act in connexion with this constantly recurring mass of information, and his consequent sense of responsibility has sometimes rendered the medical officer of health, in his plans for improvement, vulnerable in the eyes of general practitioners to the charge of removing his neighbour's landmark. Such concentrated and depressing information is not so constantly before those members of the profession who are dealing for the most part with individual patients.

The medical officer of health has also to study the mass of statistical information supplied to him weekly, quarterly, and annually by the Registrar-General, and this also makes a conscientious officer more restive. Without troubling you with many figures from these and other statistics, there are some facts to which I wish to draw your attention that indicate very clearly how much room there is for improvement in the public health.

The *Annual Statistical Summary* of the Registrar-General for England and Wales demonstrates that there are far too many deaths at early ages. In the latest summary, that for 1929, it is shown that rather over one-third of the deaths of males, and nearly one-third of the deaths of females, occurred before the age of 50. Omitting deaths of infants—that is, deaths in the first year of life—there were 40,656 deaths of children under 15 years of age, and another 20,662 in the next ten years of life.

Expectation of Life

The expectation of life, according to the Registrar-General's last life table, is still only 55 years for males and 59 years for females, and though the vitality of the nation has been steadily improving generally, the life tables show almost no change at the ages of adolescence: from 30 years onwards there is but a slight increase in vitality, while at 50 the increase in expectation of life is only about two years. At advanced ages the progress is even less. In fact, the greatest part of the increase is due to the reduction of infantile mortality after the first week of life.

In the very interesting publications of the Life Extension Institute of New York you may find very plausible reasons given why there need be no limit at all to our expectation of duration of life. It is propounded that under suitable circumstances of living, and especially by means of repeated examinations to find and control defects, life could be prolonged indefinitely. Voronoff more moderately has, I believe, described 140 years as a reasonable expectation. Whatever we may think of these possibilities, we have to face the fact at present that we are still on an average far short of the 70 years of the Psalmist. We are also faced with the position that his pessimistic description of the age group 70 to 80 of his time [illegible] far too truthfully to many of the years [illegible] proportion of our population of the

Defect in Early Childhood

[illegible] ctation of life is worse than [illegible] prolonged is healthy enough [illegible] es it too often a doubtful [illegible] of sickness in the popula- [illegible] to the number of [illegible] one. The large [illegible] not die and [illegible] with forty [illegible] n who [illegible] f, must [illegible] erent health [illegible] any of the sur- [illegible] is more im-

The stated causes of the deaths in early childhood and after infancy are principally respiratory diseases, enteritis, infectious diseases, violence, and tuberculosis—in fact, causes that should be for the most part preventable. An equally or even more important cause of very many of these deaths does not appear in death certificates—namely, lack of power of resistance to disease due to want of medical attention and to improper environmental circumstances at an early age.

Other groups of figures to which I wish to draw your attention are those of illness in childhood, which are obtained from the reports of school medical officers as a result of medical inspection. In the case of children medically examined in elementary schools in England and Wales, the percentage found requiring treatment for physical defect, excluding dental defect, has been 20, year after year for the past four years, and is not decreasing. The figure for 1929 was 20.8 per cent. The principal troubles are eye and vision defects, skin diseases, enlarged tonsils and adenoids, defects of the ear and hearing, deformities, nervous diseases, tuberculosis, and heart disease. Though many of the ailments are at the time slight, they definitely affect the child's ability to study, and have their effect on its after life.

Another indication of the amount of illness among school children is the constant percentage of absentees from school. In senior schools the only legitimate cause of absence is sickness. An average attendance of 92 per cent. has been considered a good one: it is more often about 90 per cent. As regards elementary school children, therefore, we find that an average of 8 to 10 per cent. are unfit to attend school owing to illness, and one in five of those attending has some physical defect.

It is noteworthy that the children arriving at school at the age of 5 are already affected; the percentage of ailments is substantially diminished before they leave thanks largely to the measures initiated by the Board of Education and carried out by school medical officers and medical practitioners. Much of the neglect of defect at the pre-school age cannot be overcome, and will still have its injurious effect when the children become adults. A few years ago I made an investigation into the history of 504 mentally retarded children of this district who were not mentally deficient. The apparent causes were multiple in most instances, but early ill-health was the definite cause of the retardation in 47 per cent. of the cases, and a contributory cause in most of the others.

Health of Young Adult Population

As examples of the unsatisfactory position to-day of the general health, early deaths and sickness in early life stand out prominently; other examples are the vast amount of sickness shown by national health insurance reports, and the wholesale rejection of young adults who have tried to enter the Navy, Army, and Air Force Services. During the war only 36 per cent. of would-be recruits between the ages of 18 and 42 qualified for active service. This unsatisfactory position still obtains. To a question in the House of Commons last year the Secretary of State for War replied that in 1929 5 per cent. were rejected for diseases of the middle ear, and over 4 per cent. for diseases of the heart. Defects of the lower extremities, dental defect, defects of vision, and insufficient weight caused rejections in each case of 2 to 3 per cent. The defects too frequently pointed to some illness or neglect in early childhood. The only marked improvements compared with the figures of 1910 were in dental condition and chest measurements.

National Health Insurance Statistics

As regards the sickness statistics connected with national health insurance, the majority of my audience know by

experience how serious they are, even after allowing for a proportion of unnecessary consultations In any year an average of about half the insured population comes under treatment by insurance medical practitioners The claims for sickness and disablement benefit have increased continuously, and have practically doubled in recent years

For my purpose to day these examples of the state of the public health must suffice There are many others that will occur to you, such as the multiplicity of hospitals, and the enormous sale of patent medicines

FACTORS INFLUENCING THE FUTURE

In considering the outlook for the future the nature and constitution of the public whose health is to be improved is of primary importance Owing to the reduction in the birth and death rates we now have to deal with an increasingly older population than in the past This is due mainly to the decrease in the number of young people, for the life of the older generations is being prolonged but slightly According to the census records of 1901, 1911, and 1921, the proportions of the population of England and Wales under 15 years of age were 32 4, 30 6, and 27 7 per cent respectively, a decrease of about 2 per cent at each census period The proportion of older persons is correspondingly increasing

In this borough in 1891, children under 5 formed 10 per cent of the population, and in 1921 only 5 8 per cent and the proportion of children of school age has dropped from 21 2 to 16 4 per cent The average age in England and Wales at the 1921 census was 30 6 (males 29 9 and females 31 2) Ten years previously it was two years less, and in 1891 four years less Corresponding figures for the 1931 census are not yet available in detail, but it is obvious that the change is now even more marked

Death Rate

As the population becomes older the prospect of a further reduction in the death rate becomes less and less The Registrar General finds that to compare annual death rates fairly a sex and age correction has to be made in accordance with the changes that are occurring in these features By this method of correction the death rate for England and Wales for 1929 which was 11 4 per 1,000, would have been 11 5 per 1,000 if the age and sex constitution had remained as it was in 1901, the difference being mainly attributable to age alteration

heredity is escaped, are often permanently damaged mentally and physically by the consequent evil environment of their early life Persons with a tendency to mental defect react very readily to environment, the mental defective being usually amoral rather than immoral

If the present course of birth reduction continues, as it probably will do, we are nearing the time when the already diminishing natural increase of the population—that is, excess of births over deaths—will disappear entirely The annual rate of increase by excess of births over deaths per 1,000 living, which was over 14 fifty years ago, and about 12 at the end of the last century, in 1928 was 5, and in 1929, 2 9 In the present difficult circumstances this may be satisfactory, but in venturing, rightly or wrongly, to interfere with the course of nature by birth control it is certainly essential to take care that in reducing the quantity of our available supply for the future of the race, we at all events endeavour to preserve the quality of the remainder

Decrease in Infant Mortality

An alteration in the constitution of the population connected with the great decrease in infantile mortality has been caused by the survival of a large number of children who would otherwise have died Here I am less pessimistic than some of my friends Those of us working at infantile mortality are often met by the accusation that by interfering with nature in this way we are reducing the average physical and mental condition of the race No doubt some of the cases tend in this direction, but I think there is not so much in the accusation as is sometimes felt When I am told that nature's way, and the best, is the survival of the fittest infants only, I can by experience reply that in too many instances, and especially when infantile mortality was higher, the fittest themselves often had no chance of survival A selection depending on ignorance and neglect is not a natural selection, but a very artificial one The diseases which took off these infants were largely preventable and due to ignorance and carelessness, and removed as many of the fittest infants as of the weaklings Moreover, the enlightened preventive treatment which has resulted in so much saving of infant life has necessarily brought up the standard of life of infants generally It seems to me at least as safe to interfere with so-called nature in this way as to interfere

good permanently, while of those who returned many frankly admitted as a cause the attractions of the dole compared with those of greater adventure.

Unemployment

Except in strong characters, unemployment has a very adverse effect on mental and physical health. There never was a time when so much was expected from the State without individual effort, and lack of such effort and want of occupation tend to the acquiring of habits that are not conducive to health. The improvement that has taken place through better general education only partly counteracts this tendency.

Habits and Sickness

As regards habits and their relation to longevity and illness the experience of life assurance companies is valuable. With a life assurance company matters of health are business propositions, and the company has to inform itself on all points that might affect any applicant's insurability from the point of view of profit to the company. Inquiry as to habits makes up the largest field of this protective service, according to the vice-president of one of the large companies of the United States. From a review of 4,500 unfavourable reports, he states that in 32.5 per cent., or about one-third, habits were the special point, ill-health being second at 25.5 per cent. These unfavourable habits are largely connected with diet, liquid and solid, and due to lack of occupation, ignorance, carelessness, and want of self-control.

Illnesses affecting the digestive tract occupy a prominent position in invalidity of all classes. Such ailments as gastric ulcer and appendicitis are increasing in the list of causes of death. In the national health insurance sickness returns digestive ailments appear among the chief causes of invalidity. It is a truism that pathological conditions follow habits that are contrary to the course of normal physiology.

Effects of Education

Fortunately some of the changes that are occurring in the population are very favourable. Education has failed with a minority, but has resulted in a much better condition of life for the majority. The most hopeful indication of this is the improved condition of the elementary school children, in spite of the figures to which I have earlier referred. The increase in physical training and in open-air life is adding to the vitality of a large section of the race. The increased care given to children on leaving school is very important. Surroundings have greatly improved in sanitation, and in the matter of housing, although there is more to be done, the population as a whole is living in a less crowded condition and in a much better type of house than ever before.

Education of the public in health matters is progressing, and advice is more regularly sought. If the lay press, with its enormous circulation, would reproduce in popular form such definite facts as are to be found in the reports of the Ministry of Health and of the Medical Research Council, the progress would be more rapid. Sensational accounts of so-called cures for such diseases as cancer and tuberculosis do real harm. The hopelessly contradictory nature of advice so freely given as to eating and drinking prevents much notice being taken of it. Fortunately the majority rely on moderation, instinct, and the application of their own experience with skilled advice if possible.

THE MEDICAL PROFESSION AND PUBLIC HEALTH

As regards the influence of our own profession on the future of the public health, we can be optimistic. Medical practitioners, in accordance with their traditions of progress, are taking an increasing interest and a greater part in preventive medicine than at any previous period. Thanks to the work of our Association, the spirit of friendly co-operation between the branches of the profession has steadily grown and artificial barriers have been removed. In recent years there has existed a small committee of eminent and representative leaders of the profession to confer with the Ministry of Health on public health matters should occasion arise. General practitioners and medical officers of health co-operate in their work more and more as years go on. In this county borough, as in many others, there are quite a number of practitioners who, in addition to the preventive work carried on in the course of their own private practices, are giving valuable assistance in the public health service.

In its early days the public health service and the activities of the medical officer of health were almost entirely confined to the environmental circumstances of disease, a few infectious illnesses, and the application of discoveries that had been made in connexion with such essentials as pure air, pure water, and pure food. These duties of the medical officer of health are as important as they ever were, but new obligations have brought him into constant touch with members of the public as suffering individuals. This has arisen very largely from the number of persons, especially children, found to be suffering from defect, and who for various reasons, and especially want of means, received very little, if any, medical attention. It was found impossible to adhere to the principle that our duty should end when we had directed the sufferer or his guardians that the necessary medical services should be obtained, for though the advantages of the agency of the general practitioner for carrying out treatment were obvious, this was frequently not available.

The original allocation of large clinics in connexion with the public health service to men and women not long from their training schools was due to the obvious necessity for organization and freedom from other calls on their time. These points could be secured with full-time clinic officers, but could not be obtained from those in practice. Though the preventive work of the general practitioner is by no means dependent on any work he may carry out in State clinics, modifications which enable him to take part in the treatment of patients in the State clinics are so clearly advantageous that there are signs of this being more developed in the future. On the one hand, the patients themselves are entitled to the benefit of his varied experience if this can be arranged, and on the other, the experience to be obtained from these clinics would be most valuable to him in his other work. The clinics, which have been an important factor in the improvement of the public health, would be even more useful if they could be co-ordinated with an increased general practitioner service in the homes of those not in a position to obtain that service at the present time. Early tendencies require skilled guidance, and environment requires skilled supervision; if these could be secured in the home, clinics for treatment would be less necessary.

It is essential that all ill-health should receive attention, and the B.M.A. scheme to extend facilities for treatment beyond the present insured persons is therefore of the utmost importance, and should receive careful consideration. The alternatives to a scheme on these general lines are either that nothing should be done for many sick people—and this is unthinkable—or that the arrangement of medical services should be made by laymen, and this would be most unsatisfactory for both the public and ourselves. It has been truly pointed out that if the best results are to be obtained it is important that in any form of clinic, contract, or insurance practice the relation between doctor and patient should remain as nearly as possible similar to that in ordinary practice.

While efficient diagnosis and treatment will always remain essential parts of preventive medicine, the improved arrangements now made for extending teaching in the subject of public health at the medical schools are extremely important. The General Medical Council has ordained that courses of instruction in forensic medicine, hygiene, and public health should be taken concurrently with the later stages of clinical instruction, and is still considering details. Public health has hitherto been a subject very detached from the other subjects of the curriculum. This arose from the also very detached nature of the original work of medical officers of health. As far as I am aware, the teaching of the subject of public health to students of medicine has reached its greatest elaboration in the McGill University. In the curriculum of this University the course of public health and preventive medicine has been divided so that in future a portion will be taken in each of the five years of the course, and brought into close relation with the other work of the medical student in the corresponding year.

Post-graduate Study and Research

In connexion with education, the facilities for post-graduate study are rapidly increasing. The time required and the expense involved in attending post-graduate centres limit this work very considerably. I would suggest that some simple extended opportunities could be made as a supplement to the present work and to the important scheme which is now in course of development. The work of the general practitioner is very largely concerned with minor ailments of children, maternity and child welfare, tuberculosis, venereal diseases, etc. There are clinics for these in abundance all over the country, and many more of them could be made available for instructive conference and consultation.

Another feature that should continuously improve present conditions as regards health is the large amount of research work that is being carried on; its closer co-ordination with clinical practice is, however, essential. In addition to the constant and valuable study of disease by individuals, records in books and journals, and debates in medical associations and societies, the results of systematic research are most encouraging. As an instance, I may allude to such results as those experimentally obtained by Professor Edward Mellanby, Mrs. Mellanby, and others on vitamins, diet, and disease, especially as regards rickets and dental development. It has been shown that by attention to the diet of infants and children rickets and dental caries can be arrested, and even entirely prevented. I mention this one item among many to emphasize the necessity of the application of such discoveries by those whose duty it should be to look after the health of the persons concerned. A thorough application to the population of this one discovery would result in a very large reduction in the suffering of children and in the subsequent defects of adults. It would be preventive medicine in its best form, incomparably better than treating these ailments in clinics.

The want of general application of existing knowledge is one of the many reasons for consideration of the scheme for extending the present limited opportunities of the medical practitioner to get into the homes for early advice and treatment.

Importance of Physiology

Much stress has been laid on the necessity for a thorough knowledge of physiology—in other words, of the normal—in order to understand disease, and, above all, to detect early defect. The study of physiology and the normal is part of our training, and needs special attention to the individual from the time of birth, and before. In this connexion, I wonder if so much abandonment of so-called normal midwifery by the general practitioner is advisable. The only capable judge as to what is normal or abnormal in the working of the human mechanism must essentially have a good knowledge of physiology. The death returns show that the first week is the most dangerous period of human existence, and it must be beneficial to have the advantage of the doctor's knowledge from the earliest start of life.

The Auxiliary Medical Services

An important indication of progress is the attention that is being given to bringing auxiliary medical services within the reach of an increasing number of the population. This is particularly the case with regard to consultant and specialist services. One of the latest of these is a scheme to make the valuable aid of pathological examinations available for those of moderate means. These developments are largely due to the activity of our Association, whose schemes also for the extension of medical services generally, and for improved midwifery services and hospital arrangements, require earnest consideration in connexion with the future of the public health.

COMMENTARY

I have only had time to mention briefly some of the outstanding conditions that are concerned with progress; many others will occur to you. One of my objects has been to stress the extreme importance of concentrating on preserving the normal in the early part of life. Children constitute the nation later on, and a sound basis is necessary on which to found it. Sickness in early life should receive more attention. Another object has been to stress the fact that, in spite of progress, a very large section of the population is still not getting the advantage of a quick and thorough application of the various discoveries that are being made in medicine. The profession is more and more fitted to provide what is required when the opportunities can be found.

It is necessary that members of the medical profession should take a leading part in the consideration of social conditions and ameliorative measures, for any matter that may affect health must concern the profession. The presence of medical men and women in Parliament, on local government bodies, and in associations and societies that have any bearing on the subject of public health is therefore most advisable.

While claiming for members of our profession such a large share in the improvements in public health, I must mention two other agencies of the greatest importance. I refer, first, to the discoveries and the work of experts in allied sciences, and, secondly, to the immense social influences that have been employed for the betterment of health. I wish I had time to do them the justice they deserve.

CONCLUSION

In conclusion, I must ask your forgiveness for introducing various controversial subjects into this address. My excuse is that they continually arise in the course of my daily duties. I own to being a little pessimistic as to the future of public health when looked at from the aspect of some of the changes that are occurring in the constitution of the population, but if our profession advances as it has done in the past, and continues its increasing interest in preventive medicine, the adverse circumstances may be largely counteracted.

One of the methods, and not the least important one, of attaining the end we have in view—namely, the better health of the community—is by meetings such as this Annual Meeting of the British Medical Association, with its numerous scientific Sections and social opportunities for interchange of knowledge and for debating the means of increasing and applying it, and I once more thank you for granting me the very great honour of presiding on this occasion.

ARGYLL ROBERTSON PUPILS TRUE AND FALSE

A POST-GRADUATE LECTURE DELIVERED AT THE ROYAL LONDON OPHTHALMIC HOSPITAL

BY

W. J. ADIE, M.D., F.R.C.P.

PHYSICIAN, CHARING CROSS HOSPITAL, AND ROYAL LONDON OPHTHALMIC HOSPITAL; PHYSICIAN TO OUT-PATIENTS, NATIONAL HOSPITAL FOR NERVOUS DISEASES, QUEEN SQUARE

The true Argyll Robertson phenomenon is an infallible sign of syphilis; yet pupils that react on accommodation but not to light, the usual definition of an Argyll Robertson pupil, are met with in many conditions unrelated to syphilis. If both of these statements are true there must be something wrong with the usual definition. There is. It defines nothing; hence the prevailing confusion. I tell you that the sign is infallible. Others give you a long list of conditions in which it has been observed, and you do not know what to believe. I am afraid it is the same with much your teachers tell you. The chief reason for these discrepancies is failure on our part to agree upon a definition of the terms we employ; sometimes we are using different names for the same thing; in this instance we are applying the same name—the Argyll Robertson pupil—to a number of different things; often enough we are using names for nothing at all.

NEED FOR ACCURATE DEFINITION

If we are to understand one another, then, we must decide what it is we ourselves are thinking about, and what we expect others to think about when we use the term Argyll Robertson pupil; we must agree upon a definition. I give you a choice. You may define it as one that reacts on accommodation but not to light. If that is your definition, the Argyll Robertson pupil has been found not only in various forms of syphilis of the nervous system, but also in non-syphilitic congenital cerebral defects, cerebral haemorrhage and thrombosis, tumour, myelitis, arterio-sclerotic and senile dementias, internal hydrocephalus, meningitis, disseminated sclerosis, trauma, syringomyelia, progressive muscular atrophy, polio-encephalitis, encephalitis lethargica, Friedreich's disease, chronic alcoholism, diabetes, nicotine and carbon disulphide poisoning, and in various other conditions of unknown origin. I could add to this list, but I think it is long enough to show you that your sign is hardly unequivocal. It has about as much value for differential diagnosis as fever or a headache. On the other hand, if you care to base your definition on the description of the man after whom the sign is named—surely it is not fair to his name to do otherwise—you possess yourself of the most valuable of neurological signs, and one that is perhaps nearer to being unequivocal than any other in medicine.

ARGYLL ROBERTSON'S PAPER

After this introduction you may wish to know exactly what Argyll Robertson did describe. In a short, unimportant-looking paper, published in the *Edinburgh Medical Journal* in 1869, with the title "Four cases of spinal miosis, with remarks on the action of light on the pupil," he says he observed that, although the retina was quite sensitive and the pupils contracted at once during the act of accommodation for near objects, an alteration, however, in the amount of light admitted to the eye did not influence its size, and that slow and only partial dilatation ensued on the application of a strong atropine solution. If you study this statement you will see that it says much more than is implied in the usual short definition.

Time has proved that he wrought better than he knew; to his description pupils that conform in every particular in any way they are peculiar to syphilis; if they differ they are no longer certain evidence of syphilis. Let us study the essential features in detail. The sign was found in patients with "spinal miosis." There is no agreement on what constitutes miosis; let us define it as a pupil with a diameter not exceeding 2½ mm. The typical Argyll Robertson pupil is small, often very small; I advise you to retain this feature in your definition, and to be very careful in forming your opinion if the pupil is not definitely on the small side. When it is inactive to light, but not small, you will find, as a rule, that the reaction on convergence is also defective; it is then an incompletely fixed pupil, not an Argyll Robertson pupil. The patient may still be a syphilitic, but there are many other causes of an incompletely fixed pupil. The sign was present in both eyes; we know now that it may be unilateral with the same significance. If it is genuine, the Argyll Robertson pupil is always the smaller one. Again I advise caution; many unilateral Argyll Robertson pupils that have been reported were false; a pupil on one side that does not react to light but reacts on convergence is found in various non-syphilitic conditions.

The retina was "quite sensitive"—that is, vision was good. The pupil of many a blind eye reacts on convergence but not to light, but that does not make it an Argyll Robertson pupil. Further, it may react consensually; the Argyll Robertson pupil never does. I mention this because one of you told me recently that the commonest cause of an Argyll Robertson pupil is blindness. The sign is often associated with tabetic optic atrophy; in these cases the light reflex is lost, perhaps without exception, however slight the visual failure from this cause may be. If vision is defective from some other cause—for example, optic atrophy from pressure by a pituitary tumour—some reaction to light persists so long as any vision remains, and may even do so after vision is lost. In such a case the pupil reacts very sluggishly to light but well on convergence; but it is not an incomplete Argyll Robertson pupil. You may not diagnose an Argyll Robertson pupil with complete blindness, and it is unsafe to diagnose an incomplete Argyll Robertson pupil if vision is defective. The cause of the eye signs must be sought for elsewhere.

Reaction on Convergence

Typically the true Argyll Robertson pupil contracts at once and fully, often excessively, on convergence. Thereafter it dilates again promptly. I must insist on these essential features; their neglect has led to many errors. We shall return to them when we come to consider partially fixed, myotonic, and other spurious Argyll Robertson pupils. For the moment I content myself by advising you to examine the reaction on convergence very carefully; if it is defective or peculiar in any way the pupil is not a true Argyll Robertson pupil, and you are not justified in concluding from the eye signs alone that your patient has had syphilis.

Variations in Illumination

The amount of light admitted to the eye does not influence the size of the pupils. Using ordinary bedside methods they do not contract when the illumination is increased, nor do they dilate when the eye is shaded. This is another feature that often serves to distinguish the true from the false. The Argyll Robertson pupil remains the same size for days, weeks, months on end, whatever the amount of light that falls upon it; false Argyll Robertson pupils often vary in size from time to time, or dilate when shaded, and may then react briskly to light.

Effect of Mydriatics

Mydriatics cause "slow and only partial dilatation"; whereas pupils that react on convergence but not to light may often be proved false in that they dilate rapidly and completely under the influence of atropine or cocaine.

True Argyll Robertson Pupil

Small pupils, constant in size, unaltered by light or shade, contracting promptly and fully on convergence, dilating again promptly when the effort to converge is relaxed, and dilating slowly and imperfectly to mydriatics—these are the essential features. The pupils may be irregular or unequal; the lids may droop or be retracted. If these are the ocular signs, and these alone, the pupils by our definition are true Argyll Robertson pupils, and they indicate syphilitic infection of the nervous system. I need hardly say that syphilis may produce many other pupillary and ocular signs; my point is that nothing else is peculiar to syphilis.

Partial Argyll Robertson Pupil

This is firm ground. Let us see if we may proceed further with safety. If you find that the response to light, direct and consensual, in one or both eyes is certainly pathologically slow or incomplete, and the other criteria are fulfilled, this "partial Argyll Robertson sign" has the same value as the complete phenomenon, but only if vision is good.

Pupil in Encephalitis Lethargica

Some alleged exceptions to the rule that the sign is certain evidence of syphilis may now be considered. It has been stated so frequently that it may be caused by encephalitis lethargica that you have come to believe it. During the last eight years I have made a careful *ad hoc* examination in one hundred and fifty-seven cases, and the numbers given by others who have made the same investigation reach a total of many hundreds; no critical observer has ever seen a true Argyll Robertson pupil, and if it occurs at all it must be extremely rare.

Pupil in Quadrigeminal Tumours

The pupillary signs produced by tumours of the quadrigeminal region are important for discussions on the site of the lesion responsible for the Argyll Robertson phenomenon, but they can hardly be confused with the true Argyll Robertson sign as I have defined it. The pupils are rarely small, they may vary in size under observation, dilate in the dark, react after a sojourn in a dark room, dilate well with mydriatics, react imperfectly on convergence, or present some other distinguishing feature. As a rule, there is an associated conjugate palsy of upward ocular movement, papilloedema is present, and other symptoms point to the existence of a tumour.

Among a large number of others, diabetes, disseminated sclerosis, syringomyelia, chronic alcoholism, and cunningly placed vascular, inflammatory, and traumatic lesions, have been named as possible causes. All these things are possible, but you may safely ignore them. Of the recorded cases that I have looked up not one bears scrutiny.

FIXED PUPILS

Pupils that react neither to light, direct or consensual, nor on convergence, are said to be fixed. The name is unfortunate. They are not fixed like the pupil of a glass eye; indeed the normal contraction that occurs on forcible closure of the lids is often excessive and unusually easy to observe in pupils with loss of the reactions to light and convergence. Here again you see the disadvantage of using ill-defined expressions. If your records are to be of any value you must put down exactly what the pupil does in response to the various stimuli. If you write "the pupil is fixed" I do not know what the pupil has done more than I do if you say it is an Argyll Robertson pupil. This by the way. Sometimes in fixed pupils the defects are partial; when this is so the reaction to light is usually more affected than the reaction on convergence, and the findings are easily mistaken for the Argyll Robertson sign.

The causes of partially fixed pupils are as numerous and as dissimilar as the causes of supranuclear, nuclear, and infranuclear lesions of the third nerve; syphilis is merely one of them. I said that the reaction to light is more affected than the reaction on convergence; almost always the fact that the reaction on convergence is also defective will tell you that you are dealing with an incompletely fixed and not an Argyll Robertson pupil. In a small but important group of cases, however, where the signs are due to a partial or recovering lesion of the third nerve, most often traumatic, the reaction to light is completely lost, while the reaction on convergence is normal (traumatic pseudo-Argyll Robertson pupil of Axenfeld). These false Argyll Robertson pupils are usually unilateral, they vary in size from time to time, and they usually dilate promptly and fully under the influence of mydriatics.

PUPILLOTONIA

The myotonic pupil is frequently mistaken for an Argyll Robertson pupil, because it does not react to light with the ordinary tests, but does react on convergence. It is distinguished by its peculiar behaviour during convergence. It is not very rare. I have seen ten cases during the last year, and have read descriptions of about fifty others. You should know about it, because it gives rise to an unfounded suspicion of syphilis, especially when, as sometimes happens, the abnormal pupils are associated with loss of the tendon-jerks. I have seen six patients with this combination of signs, and have found descriptions of eleven isolated cases in the journals; in almost every instance a diagnosis of syphilis of the nervous system had been wrongly made. The myotonic pupil is most often unilateral; it is then almost always larger than its fellow; it may be oval, with the long axis horizontal or vertical; it is often large, sometimes quite small, but never miotic. When ordinary bedside methods are used the reaction to light, direct and consensual, appears to be completely, or almost completely, abolished; after a sojourn in a dark room, however, the pupil dilates, and on subsequent exposure to diffuse daylight contracts very slowly again; this contraction may proceed until the pupil becomes considerably smaller than it was before it dilated in the dark; thereafter it dilates slowly again to its original size. Even after a long stay in a dark room the pupil may not contract to the usual short illumination with a pocket torch; a long exposure may be necessary—in two of my cases I had to expose the eyes for several minutes to bright light at the window on a sunny day, before the size of the pupil changed appreciably.

During the act of accommodation for a near object contraction of the pupil, sometimes after a short delay, precedes slowly through a range often greatly in excess of the normal; the larger abnormal pupil may then become smaller than its normal fellow. In all the cases that I have examined, and in a large majority of those reported by others, the pupil remained small for some seconds up to several minutes after the act of convergence had ceased; rarely it begins to dilate again at once; in both cases dilatation proceeds at an even slower rate than did contraction, so that many minutes may elapse before the pupil regains its usual size. Sometimes accommodation is affected in the same way; it is noticed most often during relaxation; after a near object is looked at some seconds elapse before distant objects become clear. I will not burden you with more details about this interesting phenomenon, but I must emphasize the points on which it differs from the true Argyll Robertson sign. It is most often unilateral; the pupils vary in size from time to time; they are never miotic; the reaction to light, though absent to ordinary tests, is not really abolished; the pupil dilates in the dark; the reaction on convergence is peculiar; accommodation, though normal in range, is

sometimes slow ; and prompt and full dilatation occurs with mydriatics.

The cause of this phenomenon is unknown, and it is probably a manifestation of a disorder *sui generis*. Certainly the pupillary reactions differ essentially from those with which we are most familiar—namely, the Argyll Robertson phenomenon, fixed pupils, and ophthalmoplegia interna. The Argyll Robertson pupil is usually bilateral, the myotonic pupil unilateral ; the first is typically small, the latter large ; the one is always syphilitic in origin, the other never. Similar considerations distinguish it from fixed pupils and ophthalmoplegia interna. The iris of the myotonic pupil is not paralysed, and if the stimulus is intense enough or sufficiently prolonged the pupil contracts through a range wider than the normal ; accommodation, too, may be slow, but the range is normal. The terms " internal ophthalmoplegia " and " iridoplegia " that have been used in the titles of papers dealing with myotonic pupils are inapplicable and confusing.

Mr. Foster Moore, to whom I am greatly indebted, has seen about twenty patients with myotonic pupils, and has allowed me to examine some of them. He applied the term " non-luetic Argyll Robertson pupil " to them, but is not satisfied with it. According to the view I am expressing here it is a contradiction in terms ; moreover, there are many other non-luetic spurious Argyll Robertson pupils than the one he has described. As we must use linguistic shorthand, " myotonic " pupil is perhaps the best name, but you should think of the word myotonic as being in inverted commas, because the reaction is not the same as the myotonic reaction in Thomsen's disease. Its importance, whatever you choose to call it, is that it gives rise to an unfounded suspicion of syphilis.

I might mention other non-luetic conditions in which the pupils react on convergence but not to light, but I think I have said enough to convince you that pupils conforming to this definition occur in many dissimilar disorders, and that this definition is of little value ; certainly it does not define what Argyll Robertson described. I hope, too, that your own experience will prove to you that the true Argyll Robertson pupil, as I have defined it, is, as near as may be in an imperfect world, an infallible sign of syphilis of the nervous system.

COMPLETE ERADICATION OF THE THYROGLOSSAL TRACT

BY

HAMILTON BAILEY, F.R.C.S.

SURGEON, ROYAL NORTHERN HOSPITAL

(With Special Plate)

In an adult it is usually a simple matter to tell at a glance if a thyroglossal fistula is an old-standing one. Fistulas originating during infancy—they are rarely congenital—have their orifices situated low down in the neck ; furthermore, the crescentic appearance of an old fistula is characteristic (Fig. 1, Special Plate).

ANATOMICAL CONSIDERATIONS

The thyroglossal tract extends from the isthmus of the thyroid gland to the foramen caecum. The ramifications of a fistula connected with this tract can often be demonstrated by injecting lipiodol prior to a lateral radiogram, and the duct can sometimes be shown to pass right into the back of the tongue (Fig. 2, Special Plate). Unless the entire tract is removed, secreting epithelium is left behind, and after a short interval the fistula reappears (Fig. A). In the case of thyroglossal cysts the story of incomplete extirpation of the tract is much the same, for simple removal of the cyst is followed by a fistula which continues to discharge. In a review of thirty cases[1] of thyroglossal fistula I found that seventeen followed an operation for a thyroglossal cyst.

OPERATIVE PROCEDURES

Sistrunk's method of ensuring that the whole tract is removed is an excellent one, which should be looked upon as the standard operation for dealing with these otherwise troublesome cases. It is only by completely eradicating the whole tract in every case of thyroglossal

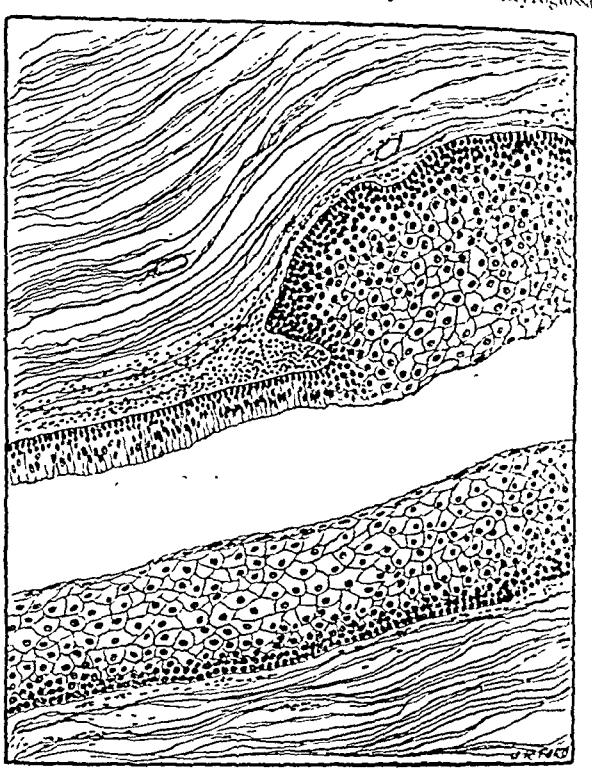

FIG. A.—Section of a thyroglossal fistula in the region of the hyoid bone, showing variations in the type of epithelium which lines the tract. (Section by Dr. P. O. Ellison.)

cyst as well as in every thyroglossal fistula that a perfect end-result may be confidently expected. The details of the operation are as follows. Through an elliptical transverse incision about the orifice, the tract is dissected up to the level of the hyoid bone. There is nothing to disturb the even tenor of the dissection up to this point. The body of the hyoid bone is then cleared on either side and divided on the left and the right so as to free a little more than a quarter of an inch of the centre of the bone, to which the tract is attached. Incidentally, even in a child, the hyoid is a tough little bone, and full-sized bone-cutting forceps are necessary to divide it cleanly. The wedge out of the hyoid is lifted up and the thyrohyoid membrane displayed. Dissection is now continued in the direction of the foramen caecum, but this time without attempting to isolate the duct (Fig. B). The tissues are cored through, allowing about a third of an inch on every side of the duct. The foramen caecum lies upwards and backwards at an angle of 45 degrees from the body of the hyoid bone (Fig. C), and it is along this line that we proceed until the cavity of the mouth is reached. This completes the dissection, and one lifts away *en bloc* the skin about the orifice of the tract ; the tract as far as the hyoid bone ; the centre of the body of the hyoid bone ; a disk of muscle from the mylohyoid muscle ; a disk of muscle from the geniohyoid muscle ; a tubular portion of the very heart of the geniohyoglossi muscles, and the foramen caecum.

Within this vermiform length of tissues, a seemingly sorry prize for so much labour, lies every secreting cell of the thyroglossal tract. Nothing short of this radical extirpation will guard against recurrence.

RECONSTRUCTION

The geniohyoglossi are brought together with sutures, care being taken that the first stitch completely shuts the opening into the mouth. The tissues about the hyoid bone are approximated, but there is no necessity to attempt to bring the cut edges of the bone together. A small drainage tube is inserted and the skin closed, mainly with Van Herff's clips, which in my experience is better than any other method of approximating the skin, as it gives the most satisfactory scar.

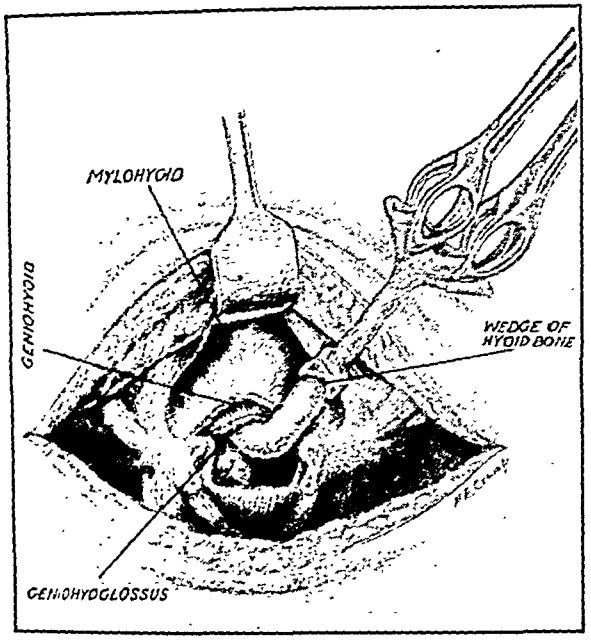

FIG. B.—The dissection nearing completion.

When the tract is a long one, as when the orifice is situated at some distance below the hyoid bone, the operation is considerably facilitated by making a second transverse skin incision above the first. For instance, in Case III (see below) the fistula was dissected out until the hyoid bone was reached, then a second skin incision was made at this level, and the dissected tract threaded through from the lower to the upper level, after which the dissection was begun anew.

THREE CASES OF THYROGLOSSAL FISTULA TREATED BY SISTRUNK'S OPERATION

CASE I

A married woman of 31 had a thyroglossal cyst excised at the age of 14. Shortly afterwards a fistula appeared in the region of the hyoid bone. Two years later the fistula was excised, but no sooner had the stitches been removed than excretion commenced to issue from the centre of the wound. For fifteen years the fistula continued to discharge, and she wore a little pad to absorb the moisture. Recurrent attacks of inflammation occurred at varying intervals. She presented herself as an out-patient during one of these attacks. After the inflammation had subsided, the indurated tract of the previous operations was excised and Sistrunk's operation performed. The result was highly satisfactory.

CASE II

A schoolgirl, aged 12, came to me with a history that one year previously a thyroglossal cyst had been excised from below the hyoid bone. Almost at once a fistula developed just below the hyoid bone. Repeated attacks of inflammation had occurred during the past few months. Sistrunk's operation was performed. The wound healed well. On examination six months later it was reported that the wound had healed perfectly.

CASE III

Mrs. S., aged 28. At the age of 7 a thyroglossal cyst had been operated upon and a fistula resulted. Three further operations were performed in her girlhood—apparently local excision of the area or incision during the acute attacks of inflammation. For the previous nine months, she stated, the fistula (*Fig. 1, Special Plate*) had leaked continuously. Sistrunk's operation was performed, a second transverse skin incision being made at the level of the hyoid bone. Intratracheal ether was given in this case, and I formed the opinion that it is the best anaesthetic for the operation.

It is interesting to note that no disability follows removal of the centre of the hyoid bone. Within forty-eight hours the patient is able to protrude the tongue normally and to swallow without pain. The body of the hyoid bone apparently regenerates, for in one of my cases one year after Sistrunk's operation had been performed for a thyroglossal cyst a radiogram showed the hyoid bone intact.

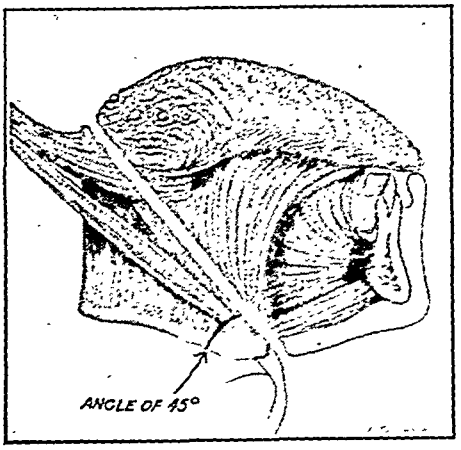

FIG. C.—The path of the dissection after passing the hyoid.

PREVENTABLE DENTAL DEFORMITIES*

BY

R. H. McKEAG, M.B., B.CH., B.DENT.SC.

(With Special Plate)

The dental surgeon is called upon to correct rather than to prevent malpositions of the teeth. So often does this occur that the accepted classifications of mal-occlusion, or abnormal relationship of the teeth, ignore the cause entirely, and are framed to facilitate treatment. By the time the dentist sees the patient it is usually the case that the mere removal of the cause is insufficient to bring about a cure, and indeed often the original cause has itself disappeared by then.

On investigating the subject I was amazed to find that the vast majority of orthodontic cases in my practice could have been prevented had the defect been noticed at an early stage by someone having the necessary knowledge and authority. I am therefore proposing to put before you the main causes of preventable dental deformity, and to illustrate some of the results following neglect of simple precautions. The models which I ask

* A paper read at a meeting of the Bath and Bristol Branch of the British Medical Association in conjunction with the Bristol and District Section of the British Dental Association.

you to examine are not those of particularly bad cases, but no exaggeration is required to demonstrate the deformities which occur. They are all from patients in my own practice seen within the last few months. There is no need to dwell on the ill effects of the deformities on the child's physical and mental welfare.

MOUTH-BREATHING

The first important cause of deformity is mouth-breathing, which may be due to habit or to some temporary or permanent obstruction to nasal respiration. It is most necessary to distinguish between habit, probably formed during a temporary obstruction due to catarrh, and one of the more permanent partial obstructions which come into the domain of the nose and throat specialist. My rough-and-ready method of differentiation is to tell the child to keep his mouth tightly closed and to jump on and off a low hassock a number of times. If the child can do this exercise with the mouth closed for a reasonable space of time I am convinced that there is no obstruction. If not, I advise a visit to the doctor. I admit that this test takes no account of defective heart or lungs, but these are as much outside of the dentist's province as are adenoids or a deflected nasal septum. Where no obstruction to normal breathing is present the child should be encouraged to breathe through the nose, and the parent can give gentle reminders when necessary. If this is insufficient to break the habit, the dentist can make a light vulcanite plate to be worn at night, fitting in front of the incisors and behind the lips.

The commonest type of deformity resulting from mouth-breathing shows a narrow, high upper arch, protruding upper incisors, and a receding chin, and is often followed by serious periodontal disease of the lower incisors, and later of the upper ones also. The normal negative pressure in the mouth being lost, the palate develops in an upward instead of a horizontal direction, and consequently narrowing or lack of development of the nasal air passages occurs. When this bony change has taken place the removal of the original obstruction does not effect a cure, as another obstruction has taken its place. It is thus of the greatest importance that enlarged tonsils and adenoids should be removed at the earliest possible moment.

Mouth-breathing associated with inflammation of the tonsils may produce a rarer but more disfiguring condition in which the lower teeth come outside the upper, and the child has a " bulldog " appearance. The reason for this is somewhat obscure, but it seems that the tongue and lower jaw are pulled forward by the muscles to avoid pressure on the inflamed tonsils by the posterior part of the mandible and the palatoglossus muscle, which is attached to the side of the tongue and forms the anterior part of the fauces. The anterior relationship of the lower jaw, if maintained for some time, becomes fixed by the interlocking of the cusps of the teeth.

THUMB-SUCKING, LIP-BITING, AND TONGUE-BITING

Thumb-sucking, and, to a lesser degree, lip-biting and tongue-biting, are responsible for another large group of deformities. In these the action is purely mechanical and easily followed. Thumb-sucking produces a splaying forward of the upper front teeth, and gives the unfortunate child a vacant appearance, which is a perpetual and dreadful handicap in his life. *Lip-biting is very common*, and may be associated with tongue-biting ; the latter by itself usually causes a gap between the upper and lower front teeth, but the child may habitually keep the tongue between the back teeth of the upper and lower jaws on one or other side, with a resultant displacement of the teeth on that side.

PREMATURE LOSS OF TEETH

The third main group is caused by the premature loss of teeth, either deciduous or permanent. When the temporary teeth are lost early through decay, or from any other cause, the growth of the jaw is arrested and crowding of the permanent teeth follows. This crowding not only produces mal-occlusion and the consequent lessening of chewing and biting power, but it renders the teeth much more liable to decay, as the great natural cleanser of the mouth, the tongue, is obstructed in its work, and corners and angles in which food may lodge and decompose are provided. Even now there are hundreds of thousands of parents who firmly believe that the loss of the milk teeth is unimportant, because they will be followed by the second set. The proper growth of the jaws is to a very great extent dependent on the presence of the teeth. Where a temporary molar is lost on one side before its time, the permanent molar in its growth drifts into the space provided, *and the permanent* bicuspid, which should occupy the position of the deciduous molar, is crowded out of the line. The bone of the jaw develops less than on the side where the deciduous teeth have been retained until the permanent teeth under them are ready to erupt.

The loss of the lower first permanent molars, and often the upper ones also, at an early age is extremely common. These teeth erupt when the child is about 6 years old, and are not noticed as permanent teeth by the parents, as none of the temporary teeth are shed until a year later, and the temporary molars are not shed until the child is 10 or 11. These first permanent molars are especially liable to decay for a variety of causes. They have deep furrows on the face of the crown which trap food, and these furrows are often badly calcified. Their calcification takes place during the first two years of extrauterine life ; the newly born baby does not always take to its food at once, nor is the process of weaning always unattended by digestive troubles. The eruption of the deciduous teeth also is, on occasions, a source of interruption to the steady flow of nutriment to the calcifying teeth. The loss of the lower first permanent molars results in a falling back of the lower front teeth, which is extremely difficult and often impossible to cure. The lower lip then has room to get behind the upper front teeth and pushes them out, the result being a greater deformity than even that caused by thumb-sucking.

OTHER CAUSES OF DEFORMITY

I purposely avoid mention of direct damage done in the mouth by the surgeon—namely, in certain operations for cleft palate—as this is always, I am sure, unavoidable, but there is one slight surgical operation which might with advantage be performed more frequently by any doctor who happens to notice the condition. I refer to the cutting of the frenum of the upper lip when this is attached too low down on the alveolus. When this happens and is unremedied the two central incisors are unduly separated.

Another cause, or contributory cause, of dental deformity is lack of muscular development of the tongue and lips. The position of the teeth is controlled much more than was formerly thought to be the case by muscular action. This should be borne in mind when deciding on the time and method for hare-lip operations.

SUMMARY

Mouth-breathing, whatever its cause, can often be noted and steps taken to cure it by the doctor, but this must be done at an early stage. Similarly, thumb-sucking, lip-biting, and tongue-biting can be investigated by the doctor, and the parents warned of the probable conse-

quences There is no need to emphasize the necessity for care in the feeding of the mother and young child Milk and cod liver oil help to produce well calcified teeth Hard food develops the jaws, and allows room for the full complement of thirty two teeth Apples and other fruit cleanse the teeth from acid producing carbohydrates Should decay occur, whether it be in deciduous or in permanent teeth, the sooner the child is brought to the dentist the better It is far easier for the medical profession than for the dentists to educate the public and stamp out the wicked fallacy that the first teeth do not matter much

The advent of the specialist has robbed us to some extent of the family doctor who cared for his patients from the cradle to the grave, and whose advice was as freely given to avoid disease and deformity as to effect a cure when they were present, but even now there are many opportunities in which a few timely words from the doctor could save his patients from many of the deformities of mal occlusion, which are very real, and none the less serious because they are so common

SEPTIC THROMBOSIS OF THE LATERAL SINUS IN CHILDREN

WITH REPORT OF A CASE COMPLICATED BY METASTATIC INFECTION OF THE HIP JOINT RECOVERY AFTER SEVEN OPERATIONS AND PROLONGED ILLNESS

BY

DOUGLAS GUTHRIE, M.D., F.R.C.S.

SURGEON TO THE EAR AND THROAT DEPARTMENT, ROYAL HOSPITAL FOR SICK CHILDREN, EDINBURGH

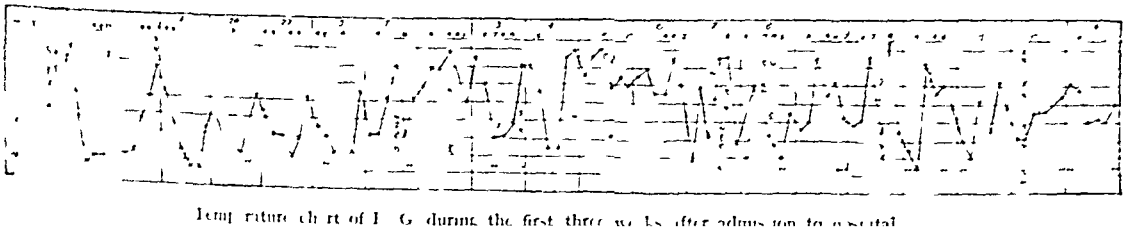
AND

D. STEWART MIDDLETON, M.B., F.R.C.S.

ASSISTANT SURGEON, ROYAL HOSPITAL FOR SICK CHILDREN, EDINBURGH

(*With Special Plate*)

Septic thrombosis of the lateral sinus is rare in childhood In a series of 500 consecutive cases of middle ear suppuration (reported by one of us[1]), including 80 cases



AN UNUSUAL CASE OF TYPHOID PHLEBITIS OF THE LATERAL SINUS

E. G., aged 8, was the youngest child of a family of six, and had always been healthy until she had scarlet fever in April 1929 She then had discharge from the left ear, which continued off and on afterwards Adenoids and tonsils were removed in February, 1930 Eight days before admission to hospital she was seized with vomiting, headache, and fever The family doctor treated this as gastric influenza, which was prevalent in the district The vomiting abated, but the headache continued and the day before admission she had a temperature of 101° F. and a severe rigor, during which she was evanosed and had a feeble pulse Absence of ear discharge and of mastoid tenderness was remarked upon by the doctor Admitted to Meikleham ward September 24th, 1930

September 24th, 1930.—Patient has vomited once since admission is very drowsy, and resents being moved Pupils both equally dilated Knee jerks feeble No ankle clonus or Babinski Slight stiffness of neck muscles on making passive movement Glands on left side of neck behind angle of jaw slightly enlarged and tender A little fetid sticky pus in left ear Tympanic membrane not clearly visible, but seems to show large central perforation No mastoid tenderness, swelling or oedema On account of tenderness in neck and rigor, septic sinus thrombosis suspected and operation advised

First Operation, September 24th (9 p.m.).—Under ether anaesthesia usual mastoid incision was made, and prolonged downwards along anterior border of sterno-mastoid muscle Superficial tissues appeared normal On removing outer mastoid wall, black fetid fluid escaped Sinus found to be collapsed with greenish sloughy appearance, extending from knee of sinus to jugular bulb, which was also full of fetid black fluid Upper end of sinus exposed until healthy blue wall seen Bled freely on opening here Iodoform worsted packing inserted Internal jugular vein ligatured in neck with some difficulty, owing to small dense mass of lymphatic glands Vein was washed through from above with saline dislodging dark turbid fluid and a little clot This fluid was afterwards found to contain *Streptococcus haemolyticus* in pure culture Tube left in upper end of jugular vein in neck Radical mastoid completed, but no plastic treatment of meatus White caseous material filled the tympanum No ossicles found Bipp applied and wound loosely packed without stitching

September 25th.—Vomited once this morning No rigor Is dull and listless

Temperature chart of E. G. during the first three weeks after admission to hospital

to jugular bulb in mastoid wound, dislodging some pus. Eusol dressings.

October 4th.—Patient looks very pale and ill. First complaint of pain in groin over right hip-joint. Temperature has risen to 105°.

October 5th.—Packing in sinus loosened, free bleeding. Temperature 103° to 104°, remained up continuously. Looks very ill—so ill that operation on hip is not advised.

October 8th.—Still has slight rigor every night, and is extremely ill, though wound appears healthy and is now granulating. As the symptoms suggested continued thrombosis it was decided to explore lower end of jugular, which had been ligatured in neck, before incising hip-joint.

Third Operation, October 8th.—Ethyl chloride and ether anaesthesia. Jugular explored and tied lower down, but no thrombosis found. After operation patient collapsed and was almost pulseless; cyanosed. Rallied a little after pituitrin had been injected.

October 9th.—Oedema of right eye; eyelid tense and eye quite closed. Pulse feeble, and child obviously extremely ill.

October 10th.—Oedema of eye worse, and also oedema of right side of face, but not of scalp. Blood transfusion, 5 p.m., 150 c.cm. of citrated blood from brother, aged 24, into vein in left ankle. At 8 p.m. temperature rose to almost 106°, but no rigor or perspiration.

October 12th.—Oedema of scalp, all over vertex, worse on right side, extending to right side of face. Right eye closed, lid very tense. Left eye partly closed.

Fourth Operation, October 13th.—Gas and oxygen. The condition of the hip, which had been overshadowed by the other symptoms, became worse and demanded attention. Abscess in right hip incised and drained by incision above trochanter. About half a pint of foul-smelling pus evacuated.

October 14th.—Packing removed from upper end of sinus, which did not bleed, but was apparently healthy. Temperature 100° to 102°.

October 16th.—Adexolin capsules (two-hourly for twenty-four hours) were given for three days, but they were discontinued as they appeared to cause nausea.

October 18th.—General condition slightly better. Taking food well. Wound clean and granulating. Scalp still oedematous. Right eye closed, left partly. Hip draining well; still considerable discharge of pus. Child much wasted. Temperature still 100° to 102°.

October 19th.—Less oedema. Mainly now on vertex. Right eye can be slightly opened now.

October 20th.—Radiogram taken (Fig. 1, Special Plate), and upper femoral epiphysis found to be separated. (Child had been too ill to be moved.) "Put up" in double abduction with extension.

October 22nd.—General condition much better. Taking food well. Less drowsy; mentally bright. Colour better. Oedema of vertex less, and right eye only slightly swollen.

October 26th.—Oedema almost gone. Temperature 100°. Tongue clean. General appearance improved, though patient very much wasted. Dr. Sinclair reports double optic neuritis.

November 4th.—Rather worse last few days and temperature higher. Profuse foul discharge from abscess of hip.

Fifth Operation, November 4th.—Gas and oxygen anaesthesia. Exploration of hip-joint through an anterior incision and removal of head of femur, which was lying loose in abscess cavity.

November 12th.—General condition not so good. Pulse feeble. Extremely wasted and pale. Mastoid wound quite clean and healing. Hip abscess discharging profusely.

Sixth Operation, November 12th.—Gas and oxygen. The hip-joint again explored, and various pockets found tracking down among adductors of thigh. Through-and-through drainage was established from joint to inner side of thigh.

November 13th.—Blood transfusion from brother, 150 c.cm. citrated blood.

November 14th.—Slight oedema of vertex.

November 20th.—Much less discharge from hip. Mastoid wound clean. Still variations of temperature, 98° (morning) to 102° (6 p.m.). Pulse rather rapid, 160 or less.

December 3rd.—Temperature now nearer normal, seldom above 100°. The extensive mastoid wound is healing and now quite superficial. Still a good deal of discharge from hip.

January 3rd, 1931.—Temperature has been normal for ten days. X-ray shows commencing ankylosis of hip in abducted position. Mastoid wound healed; slight meatal discharge. Hip still discharging. General condition greatly improved.

January 10th.—Dr. Sinclair reports that there is now no sign of optic neuritis.

March 6th.—Slow convalescence followed date of last note, interrupted by occasional evening rise of temperature. By February the hip wounds had healed and the joint was immobilized in a plaster case.

March 25th.—For the past fortnight has had swelling of right side of neck, which was mainly in parotid region to begin with, and the appearance strongly suggested mumps, but recently has softened and formed an abscess, which is now obviously an abscess of the carotid chain of cervical glands.

Seventh Operation, March 25th.—Abscess opened just anterior to sterno-mastoid, at cricoid level, and one ounce of thick blood-stained pus evacuated. Rapid healing followed.

March 31st.—Plaster removed. X-ray plate (Fig. 2, Special Plate) shows bony ankylosis in good position with comparatively little shortening.

Progress.—The subsequent recovery of the patient was uneventful. Early in April, 1931, she was allowed to get up, and soon regained the power of walking, though naturally this was a difficult matter at first. Her general health improved steadily, and at the end of the month she was allowed to return home.

COMMENTARY ON THE CASE

We do not propose to give an account of septic sinus thrombosis, or to repeat the facts which may be found in any textbook of otology. There are, however, certain features of the above case which call for special comment.

Diagnosis

This is often a difficult matter in the absence of definite ear symptoms, and the liability to error increases during an influenza epidemic, as the general symptoms may exactly correspond to those of a certain type of influenza. One cannot too strongly insist upon the routine examination of the tympanic membranes in all sick children. The otoscope is as essential as the stethoscope in paediatric practice. The characteristic rigors are not always present in children, although the "alpine peak" temperature chart is a constant phenomenon, if the temperature is taken at regular frequent intervals. In the present case the rigors were unaccompanied by the profuse perspiration noticed in adult patients. The tenderness of the neck and sensation (on palpation) of a cord in the neck is caused by the enlarged glands rather than by the thrombosed vein. Sometimes, as in the case we have reported, there may be no obvious discharge from the ear, and the otitis may be revealed only by careful inspection.

Extension of the Thrombo-phlebitis

Persistence of the rigors and high temperature after the first operation necessitated a second exposure of the sinus eight days later, when it was found that the septic process had extended upwards. This is not uncommon, and as a rule it is found that the extension of infection affects the upper end of the sinus rather than the lower end of the jugular vein. In the present case, even after the upward extension had been dealt with, the symptoms continued. At this stage the child was extremely ill, and it was difficult to determine whether the arthritis of the hip-joint was responsible for the high temperature and rigors. It was decided to examine the jugular vein; this proved to be healthy. A few days later the patient rallied slightly, and a large abscess of the hip was opened. With a view to minimizing the risk of an upward extension of the thrombo-phlebitis, which may, as in the present case, demand a second operation, we suggest the following modification of technique. Instead of follow-

the thrombosed vessel upwards until healthy tissue is reached and then introducing packing through an infected tract, the reverse procedure should be adopted. Thus, before opening the sinus it should be traced backwards until an area of healthy dural wall is exposed. A small incision is made here, and packing is introduced so as to check the haemorrhage and to occlude the sinus, and then the infected vessel is slit open and treated in the usual manner.

Oedema of Face and Scalp.

The day after the third operation (re-ligation of jugular) there appeared a massive oedema of the face and eyelids on the right (opposite) side. Within two days this had extended all over the scalp, which presented a curious appearance, as though the child were wearing a cap; this oedema persisted for ten days, and then gradually disappeared. The phenomenon is difficult to explain, and still more puzzling is the question why the eyelid of the side opposite to the ear lesion should have become so swollen. There was no protrusion of the eyeball and no chemosis. We have failed to find any similar case recorded in the literature of sinus thrombosis. The oedema of the vertex reappeared after the second blood transfusion, but lasted only for a few days.

Metastatic Infection of the Hip-joint

The hip is the joint most frequently involved when metastatic arthritis follows thrombosis of the lateral sinus, the infection commencing as an osteomyelitis of the neck of the femur, and almost immediately infecting the joint cavity. The hip infection is liable to be of the "quiet" variety met with in cases of multiple osteomyelitis, the arthritis developing insidiously, and causing few symptoms until destruction is well advanced. This fact is well worth remembering in all cases of septic thrombophlebitis, in order that regular examination of the joints may be carried out, and the joint lesion diagnosed at an early stage.

The result of an arthritis such as this varies with the age of the patient. In older children—for example, the patient under discussion—the upper epiphysis of the femur is very apt to separate, and requires removal as a sequestrum before healing will occur. A firm bony ankylosis results, and if this happens in a position of abduction an excellent functional result may be expected. In younger children, however, where the head and neck of the femur are largely composed of cartilage, a dorsal dislocation of the hip is apt to take place. The head and neck of the femur then frequently absorb, irrespective of whether the dislocation has been reduced or not, and the child is left with considerable shortening, a fibrous ankylosis, or even a complete false joint. In these cases function is likely to be rather poorer, and chronic osteoarthritic changes may supervene in the false joint when the patient reaches adult years.

Effect of Blood Transfusion

The patient was transfused with 150 c.cm. of blood from her brother on October 10th, and again on November 13th. On each occasion the transfusion appeared to be followed by definite improvement in the patient's condition. The bloods of donor and recipient were matched directly against each other, and the ordinary citrate method was employed. It is our experience that blood transfusion, whether of citrated blood, whole blood, or of so-called "immune" blood, is of doubtful value in the treatment of acute septicaemic or pyaemic conditions. If, however, the patient survives for a period of some weeks, a progressive secondary anaemia develops, and at this stage transfusion appears to raise the patient's power of overcoming the infection. Repeated transfusions of small quantities of blood are of more benefit than a large quantity on one occasion. We cannot be so dogmatic in regard to the administration of concentrated vitamins (adexolin or radiostoleum) or of collosol manganese, although those remedies deserve further trial in similar cases. The intramuscular injection of blood from a donor in 10 c.cm. doses is another form of treatment which has been recommended, and which was employed in one of the cases related below, unfortunately with little effect.

Psychic Phenomena

It is worth while recording that throughout the severe illness the child preserved a happy and hopeful demeanour, complacently and invariably replying with the word "Better" when asked how she was feeling. May not this mental outlook have assisted her to recover?

FOUR OTHER CASES OF SINUS THROMBOSIS IN CHILDREN

The following brief notes of similar cases observed at the Royal Hospital for Sick Children during the past three years are appended in order to complete the record. Curiously enough, no case of "aural bacteriaemia" without sinus thrombosis has come under our notice. During the same period three cases of perisinus abscess and one case of cavernous sinus thrombosis have been seen by us. In none of the cases of perisinus abscess did the sinus appear to be thrombosed; in no case was it opened; all three patients recovered.

CASE I

Lilias L., aged 8, had discharge from the left ear for six months. For three days prior to coming to hospital she suffered from headache, vomiting, and drowsiness, and the day before admission she had a rigor. Profuse thin purulent discharge from left ear, large central perforation of tympanic membrane, no mastoid tenderness or oedema. At operation fetid greenish pus was found in antrum and cells. The lateral sinus was collapsed, and covered with greenish exudate. It contained a clot extending from the knee to the jugular bulb. The usual operation was completed, and the jugular vein was ligatured. Pus contained streptococci. The child rallied next day, and had no further rigor or rise of temperature, but died suddenly two days after operation. Post-mortem examination revealed toxic changes in all organs. No meningitis. No cerebral abscess.

CASE II

Jean McS., aged 9, had pain in her left ear five days before admission, and a day later profuse discharge from ear. The pain continued, and the temperature rose to 102° or 103° each night. Vomiting and restlessness. No rigor. Mastoid oedema and tenderness. Prominence of posterior wall of meatus, which was almost occluded. At operation, no superficial abscess. On removing cortex, a cavity the size of a hazel nut was entered, containing thin, greenish, very offensive fluid. The antrum contained this fluid, and also a little caseous pus. The lateral sinus lay bare in the inner wall of the cavity, but was of healthy blue appearance. The lower part, however, was covered with granulations, and was unduly firm to the touch. It was therefore opened, and, although the upper end bled freely, the lower end was occluded by a large blood clot which appeared to extend upwards from the jugular bulb. The clot was removed. The jugular vein was ligatured in the neck, and although it contained no blood clot, it was found impossible to syringe through from the bulb in the neck towards the upper end of the jugular vein. The temperature remained at 100° to 102°, and there was not much improvement following operation. Collosol argentum (1·2 c.cm.) was injected intravenously each day, but this had little or no effect. No blood transfusion was practised. The child never rallied, and died eight days later. No post-mortem examination.

CASE III

Margaret T., aged 6, had suffered occasionally from earache prior to removal of tonsils and adenoids. A month after the operation, severe earache in left ear. Left tympanic membrane was red and bulging, and was therefore incised. The ear discharged freely, but pain continued and was accompanied by rise of temperature to 100° each afternoon, falling to normal in morning. No rigors. Mastoidectomy revealed a little muco-pus in cells and antrum, and also swollen red mucosa. Lateral sinus was exposed, and, although it appeared healthy, was incised; it bled freely and contained no clot, although the wall was thicker than is usual. As the lower end did not bleed, after packing off the upper end the jugular vein was ligatured in the neck. The case was regarded as a thrombosis of the jugular bulb. Notwithstanding those measures, the daily rise of temperature continued. It was unaccompanied by rigor or perspiration. A week later the lateral sinus was more freely exposed, and the upper end was found to be inflamed and thrombosed to within half an inch of the torcular. Indeed, the packing introduced above the clot projected into the torcular. Only slight improvement followed, and the septicaemic symptoms continued until the child died a month later. Immuno-transfusion of 250 c.cm. of blood from the father had no effect. On two occasions 10 c.cm. of blood from the father was injected intramuscularly, and the first of these injections was followed by a temperature of 105° and rigor on three successive days. Then the temperature fell to 100°, and remained at 100° to 102°, as it had averaged throughout the illness. Although the child was extremely ill during the five weeks, death was more sudden than was expected. No post-mortem examination. But for the discovery of a septic thrombus at a higher level than usual, the case would have been regarded as a primary "aural bacteriaemia."

CASE IV

Peter W., aged 11, had pain in both ears, followed two days later by discharge of pus, which ceased after a week. Then he complained of acute pain in the back of the neck, which continued for four weeks, and became more acute. He was then admitted to hospital, when it was noticed that the back of the neck was swollen and very tender on the left side. The swelling was well behind the mastoid region. Both tympanic membranes were of normal appearance. Temperature 100°. The only abnormality of the nervous system was double optic neuritis. Mr. Dott determined to explore the cerebellum. A large abscess was discovered among the suboccipital muscles. Streptococci were cultivated from the pus. There was no lesion of the cerebellum, but on exposing the lateral sinus from the posterior aspect it was found to be dilated and of yellow colour, though the outer dural surface was smooth. A needle was introduced, and some thin pus was withdrawn. The sinus was then opened and the pus evacuated. The abscess was found to extend within the sinus for a distance of 1½ inches, but the limiting clot at either end was not disturbed, as there had been no symptom indicative of sinus infection. A steady convalescence followed, and the optic neuritis disappeared. We are indebted to Mr. Dott for permission to refer to this unusual case, which will be reported more fully elsewhere.

COMMENTARY

Cases I and II presented no unusual phenomena. Case III may have been a case of aural bacteriaemia or septicaemia, in which event the operation of opening the sinus and ligaturing the jugular was ill-advised, although it appears more probable that a partial thrombus was present all the time, at a higher level than usual. Case IV was rather remarkable, and the sinus condition, which consisted of a collection of pus within the vessel between two limiting clots, might have been entirely overlooked if the optic neuritis had escaped discovery. It illustrates the importance of complete and thorough investigation of all cases in which intracranial complications are suspected.

idren: a Review 1926.

TWO CASES OF LINDAU'S DISEASE

BY

W. T. COLLIER, *M.C.*, M.D., M.R.C.P.

ASSISTANT PATHOLOGIST AND HONORARY ASSISTANT PHYSICIAN, RADCLIFFE INFIRMARY, OXFORD

(*With Special Plate*)

The syndrome known as Lindau's disease is now fairly familiar, as, apart from Lindau's original description,[1] cases are described by Cushing and Bailey in their book on blood-vessel tumours of the brain,[2] and our present knowledge has been reviewed at a recent meeting of the Royal Society of Medicine.[3]

The essential lesion in the disease is a vascular, neoplastic tumour of the central nervous system, termed by Cushing and Bailey a haemangio-blastoma, in contradistinction to the angiomatous malformations; the former is composed solely of mesodermal tissue, while the latter can be shown to contain compressed nerve tissue. The tumour may be either solid and encapsuled or partly cystic; in the latter case it usually forms a single large cyst with a small mural nodule of tumour tissue. Both types are represented in the two cases described below. Microscopically it consists of more or less well-formed blood channels and spaces, separated by closely packed endothelial cells. Cyst formation appears to be of the nature of an exudation rather than a simple degeneration. The tumour is almost unknown above the tentorium, is most common in the cerebellum, and occurs occasionally in the medulla and spinal cord.

Associated with the primary lesion there may be angiomata of the retina and malformations or tumours of the abdominal organs, as cysts of the pancreas and kidney, hypernephromata, etc. The importance of a coincident angioma of the retina lies in the fact that only when this occurs is a pre-operative diagnosis likely to be possible.

The condition is stated to be familial in about 20 per cent. of cases of the primary lesion, though only a small proportion of these have the associated lesions characteristic of Lindau's disease.

CASE I

A girl, aged 16, was first seen in the out-patient department in October, 1928, having been sent up as suffering from albuminuric retinitis. She had papilloedema of both eyes, and her urine contained a large amount of albumin.

The history was that for two to three years she had suffered from severe intermittent headaches, chiefly over the left eye, lasting one to two hours. The headaches were usually preceded by some quivering of the visual image, and she sometimes saw what she described as a bright gold dot. She also suffered from nausea and occasional vomiting at irregular times, and not necessarily related to the headaches. One sister had died of Friedreich's ataxy, and another sister suffered from similar migrainous headaches.

She was a thin but healthy-looking high-coloured girl, and nothing abnormal was found in the nervous, cardiovascular, or excretory systems during her stay in hospital (November, 1928). The urine was albumin-free; blood pressure 115/70; blood urea = 40 mg. It was subsequently discovered that the albuminuria was of the orthostatic type; the urine was albumin-free on rising, but half solid on boiling during the latter part of the day after she had been up and about.

Her eyes were examined by Mr. Adams shortly before her discharge (November 26th, 1928). He reported as follows: "Right eye: Disk is still very rosy, margin ill-defined, with much striation of nerve fibres, and also slight oedema around especially below. Left eye: Condition of disk very similar, but more marked than the right one. There is just a trace amount of swelling; the oedema is most marked above and below the disk. The whole condition seems to be subsiding and does not now suggest albuminaric retinitis." In April, 1929, Mr. Adams reported: "Both disks focus to +4 D.

the left disk seems to have the greater neuritis of the two There are many white flecks on the disk (? oedema) There is a few similar flecks on the lower nasal quadrant of the right disk No haemorrhage in either eye"

She was readmitted in October 1929 for decompression as her sight was becoming endangered The headaches had ceased but for the past three to four months she had complained of pain behind the eyes She said that she saw things surrounded by a mist and occasionally went quite blind for a short time The left eye was worse than the right She still had occasional vomiting in the morning and slight giddiness

There were still no abnormal physical signs in the examination of the nervous system except that the right abdominal reflex was brisker than the left There was no albumin in her urine on admission A left subtemporal decompression was performed on October 8th She developed bronchopneumonia and died on October 12th Two days after the operation the urine contained a considerable amount of albumin with hyaline casts in moderate numbers

Post mortem Examination.—In addition to general hyperaemia and the changes resulting from the decompression it was noted on examination of the brain that the posterior aspect of the pons was swollen and the veins especially on the left side were enlarged and turgid The medulla was uniformly swollen in its posterior and upper parts On section of the medulla transversely to the brain axis a large tumour 1½ inches in diameter was found walled off by jelly like tissue and occupying the greater part of the cross section but more on the left than the right side and leaving both pyramids the right restiform body, and a portion of the left intact The substance of the tumour was soft and extremely hyperaemic with large blood spaces At a later examination the tumour was found to commence at the lower border of the pons and to extend 2 to 3 mm down the medulla occupying the left antero internal aspect of the cross section and extending across the mid line for a short distance on to the right side (Fig 1 Special Plate) It was an obviously vascular tumour about 2 mm in width and 1 mm in depth just projecting into the lower end of the fourth ventricle and appearing to be encapsuled There was increase of fluid in the lateral ventricles On the anterior surface of the right kidney was what appeared to be a cyst 1½ mm across and projecting 1/2 mm above the surface of the kidney On section this proved to be a vascular tumour resembling the tumour in the medulla and with the shape of an equilateral triangle (Fig 2 Special Plate) It was surrounded by a well defined capsule The kidneys were otherwise healthy With the exception of the evidence of bronchopneumonia the remaining organs though deeply congested were normal

Microscopical Examination and Report

1 The tumour in the medulla is a haemangioma consisting of numerous large cavernous spaces and channels together with numerous capillaries separated by a fairly closely packed groundwork of endothelial cells The spaces are lined by endothelium and the larger ones have a wall composed of fibrous and elastic tissue some of them are partly or completely filled by partially organized fibrin There is no definite capsule but the tumour is surrounded by a layer of compressed glia which does not contain fibrous tissue (Figs 3 and 4 Special Plate)

2 The tumour in the kidney is a hypernephroma It is surrounded by a thick fibrous wall and consists of large alveoli filled by irregular finger like processes lined by cubical cells having a small nucleus and clear cytoplasm Some of the spaces however are filled with blood and the blood spaces of an angioma but are lined by the same cubical cells (Figs 5 and 6 Special Plate)

The headache became more severe and she developed uncontrollable vomiting She also complained of vertigo which had become worse since her admission to hospital and was now noticeable even in bed I saw her first on August 11th, when I found she had been unable to keep anything down except water for two to three days Temperature and pulse were normal there were no positive signs in the examination of the nervous system and no optic neuritis Lumbar puncture produced a clear fluid under slightly increased pressure which had no abnormal features Thereafter the vomiting improved On August 10th she had a fit of short duration preceded by a sensation of pins and needles in the hand On September 3rd she was admitted to the Radcliffe Infirmary The headache and vomiting continued On September 10th her disks were examined by Mr Adams, who reported "Disks are well defined There is a strand of connective tissue across the temporal vessels on the right disk Some mixed astigmatism No optic neuritis" He also reported verbally that he could find no angioma of the retina Lumbar puncture on September 15th produced a normal fluid under slightly increased pressure The patient died on September 23rd

Post mortem Examination.—There was a cyst about the size of a golf ball in the right cerebellar lobe, containing clear fluid There was also dilatation of the fourth ventricle and, slightly of the iter and third ventricle The cyst was opened on removing the brain On the inferior wall of the cyst there was a small area about 1 cm across consisting apparently of vessels The left kidney contained in its lower pole a small area apparently composed of necrotic tissue surrounded by a well defined capsule The contents were amorphous and semi solid The right kidney contained a small cyst in its upper pole The liver had a minute naevus on the surface of the right lobe The left Fallopian tube had a large multilocular cyst at its outer end with two smaller cysts attached Except for hypostatic pneumonia the other organs were normal

Microscopical Examination of Nodule in Wall of Cerebellar Cyst

"The tumour is a haemangioma It consists for the most part of fairly closely packed irregularly arranged endothelial cells traversed by a very large number of capillaries containing blood Many of these capillaries are dilated into blood spaces and a small part of the section consists only of such blood spaces separated from each other by two layers of endothelium and a scanty stroma The whole is surrounded by a thin rather indefinite capsule The tumour in the left kidney is a hypernephroma a large part of which has undergone degeneration"

SUMMARY

Two cases of capillary haemangioma (haemangioblastoma of Cushing and Bailey), in one case of the cerebellum, in the other of the medulla, are described Their association in each case with a small hypernephroma of the kidney entitles them to rank as cases of Lindau's disease, and their occurrence in two sisters illustrates the familial tendency of this disease

It is to be noted that in neither case was an angioma of the retina observed In the first case this was not specifically sought, in the second a macroscopic examination of the retina only was made, whereas an angioma may be of microscopic size In neither case was the diagnosis made during life, and it is remarkable that in the first case, with very considerable involvement of the medulla, practically the only signs of disease were those due to increased intracranial pressure

I am indebted to Mr P H Adam, honorary surgeon (Oxford

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

PSEUDO ARGYLL ROBERTSON PUPILS

AS RESULT OF LONG RESIDENCE IN THE TROPICS

Quite recently two rather interesting cases have come under my notice, which brought to mind a fact observed during my residence in the Orange River Colony and Transvaal, etc.—namely the number of cases exhibiting contracted pupils—a fact to which, owing to the environment, I did not at the time attach much importance.

The two patients, males of middle age, had similar simple symptoms: recurrent attacks of indigestion with vomiting, headache and constipation. Both had lived for periods of over ten years in the Tropics, one in India and the other on the Congo. Both had suffered from attacks of malaria, and had undergone thorough quinine therapy. Both had returned home after the war, and have remained in England *ever since*.

On examination, heart and lungs were found to be normal, as were the liver and kidneys, the urine was normal, neither patient showed any enlargement of the spleen. The recurring gastric attacks led me to run over the nervous system: the result did not help me much, and it was at this stage of the examination that the eyes came under observation. In each case the pupils were equal, but they were abnormally contracted, with sluggish reaction to light and accommodation. The sympathetic reflex appeared to be of the same type, not quite so marked in the Congo case. No trace of venereal disease could be found in the history. A blood test, however, was made, the Wassermann reaction proving negative in both cases as the films did to malaria. I saw these patients several times, the *condition of the* pupils always being the same. Morphine addiction, etc., can be ruled out in both instances. The cases exhibit, *therefore*, true *pseudo* Argyll Robertson pupils.

The question arises, What is the explanation of the unusually contracted pupils in otherwise normal cases? Is the condition a remote post-malarial phenomenon of the migraine type, as I consider the simpler symptoms are, or is a possible cause to be found in the effects of prolonged and constant exposure of the eyes to the glare of the tropical sun, and equally severe exposure of the neck (low loose collars being worn as a rule in these regions), such exposure causing prolonged and excessive nerve action on the part of the oculomotor or constrictor nerve, with attendant strain on the spiral vessels of the iris, producing permanent changes in the muscles of the iris, this result being contributed to by the effects of the sun on the *exposed* neck, primarily stimulating and secondarily paralysing to a certain degree the cervical sympathetic? It would be interesting to know if other observers have come in contact with similar cases.

ERYTHEMA NODOSUM

Recent paragraphs in the *Epitome* prompt me to report the following four cases of erythema nodosum.

A boy about 8 years of age had a typical attack of erythema nodosum, but the fever continued after the erythema had disappeared. I had him admitted to the South Eastern Hospital for Children, where he came under the care of my colleague Dr. I. M. Burns. He suspected tuberculosis as the aetiology, and confirmed the diagnosis by lumbar puncture.

A married woman, aged 36, consulted my partner Dr. H. H. Hillis about a lump in the *lower and outer* quadrant of her right breast, and he asked me to see her. She gave me the following history: She had noticed the lump six weeks previously, and it had been growing larger. It was about as large as a hazel nut and appeared to be part of the breast tissue; it was firm and apparently solid, and there was dimpling of the skin over it. Three enlarged glands could be felt rather low down in the axilla; they were somewhat unexpectedly large for such a short history. On the patient's legs were *the typical* marks of a recent attack of erythema nodosum. We felt that the breast tumour must be either a carcinoma or possibly a tuberculoma. Mr. H. S. Gray agreed, and kindly operated on the patient in Charing Cross Hospital; on section the lump proved to be tuberculous. No other tuberculous focus was found.

The third case is that of a married woman, aged about 36. I was called to see her on account of tonsillitis; this was followed by a quinzy, and the quinzy by erythema nodosum. She reminded me that I had attended her for exactly the same sequence of events ten years ago. I do not remember to have seen erythema nodosum twice in the *other person*.

About twenty-five years ago a relative of my own—one under my care—had erythema nodosum, facial palsy, and iritis, all at about the same time; these were then supposed to be rheumatic; she has had no sequel, rheumatic or *tuberculous*.

These cases support the view that erythema nodosum can be caused by a variety of toxins.

TETANY AFTER EXERCISE IN AN ASTHMATIC RELIEVED BY ADRENALINE

In the *Journal* of August 16th, 1930, R. D. Lawrence and R. A. McCance gave a clinical and chemical study of a case very similar to the one described below. This boy, like the patient they describe, is also very liable to chilblains, and his teeth are also very soft. The fillings will only stay in for a very short period.

The patient, a boy aged 13, developed asthma a good number of years ago after removal of his tonsils. The attacks used to come on about every month all through the year, but this last year he has been absolutely free. He is a clever boy, very highly strung, and very fond of all forms of athletics, particularly football and running. On May 5th, 1931, he played a game of football at the school then ran home, a distance of half a mile. He complained to his mother then that he was rather tired. Later, however, he went and played a game of cricket, then ran back to the village, a distance of a mile. From his own home he ran to his grandmother's where he was to remain the night. On learning that his uncle was arriving in the village by bus he again set off running to meet him, but, failing to find him, he ran back once more. The distance travelled altogether here would be about one mile, but half of this distance would have been uphill.

When he arrived back the last time he was noticed to be unduly short of breath and very soon after complained of severe pain which gradually increased. I saw him about five minutes after this and noted a well marked tetany. Carpopedal spasm was pronounced, the muscles of *the trunk* were also affected and Chvostek's sign was present. The knee reflexes, abdominal reflexes, and knee jerk were all exaggerated. The pain was very severe particularly over the upper part of the chest and over the cardiac region. His appearance he was very grey and *appeared to be breathing* rapidly and deeply. The respirations were 50 per min., and the pulse rate was 140. The heart sounds were perfectly normal and the apex beat was within the nipple line. There was no laryngeal spasm and no signs of asthma. Expiration and inspiration were unimpeded.

Owing to the fact that he was an asthmatic I thought I would try the effect of 0.25 c.cm. adrenaline subcutaneously first before trying anything else. About twenty seconds after the injection he said he began to feel better, and the pain was getting less. In sixty seconds he was very much better, the pain was gone, and he felt relieved in every way. The deep breathing still continued, and the pneumogram showed again he would have a great shudder, and so

smaller shivering attacks, but by another half-hour the condition passed away and he felt himself again.

This is the first attack he has been known to have had, but he said that once after a very strenuous game of football he had slight feelings very similar to this, but they passed off in about five minutes.

Ranchory. J. A. SIMPSON EMSLIE, M.B., Ch.B.

Reports of Societies

MATERNAL MORTALITY

On July 14th, at the Paddington Medical Society, Dr. G. E. OATES (M.O.H. Paddington) opened a discussion on maternal mortality. The mortality rate was higher among primiparae, and nowadays there were more first children born. The Departmental Committee had stated that 48 per cent. of the deaths were preventable, 17 per cent. were due to absence of ante-natal care, 17 per cent. to errors of judgement, 5 per cent. to lack of facilities, and 9 per cent. to negligence on the part of the patient or her friends. Local authorities urged the advisability of ante-natal care, and the ideal was for that work to be done by the doctor who would conduct the labour. Consultants and laboratory facilities were available, and some local authorities provided maternity homes. Midwives were now very well supervised.

Mr. T. G. STEVENS said that the chief causes of death were sepsis, toxaemia, haemorrhage, and accidents such as rupture of the uterus or inversion. Many cases of sepsis were autogenous, and in most cases there had been instrumental intervention. Direct infection was very rare. Sterile towels were not necessary in general practice. A mask should be worn, which need not be sterile, and a clean overall. The vulva should be disinfected. Plugging the vagina in severe ante-partum haemorrhage was the best treatment. Every case should be examined at the thirty-fourth week, when it would be possible to decide whether, in a case of contracted pelvis, it would be necessary to do Caesarean section or not. He was not much in favour of trial labour at term in cases of minor degrees of contraction. True toxaemic vomiting was very rare in the early days of pregnancy. The more severe manifestations of toxaemia could be prevented by the exhibition of sodium bicarbonate, 200 to 600 grains in a day (teaspoonful two-hourly). When the urine became alkaline and more was being passed the dosage could be lessened. If taken during pregnancy this drug also prevented the recurrence of albuminuria in subsequent pregnancies. Rupture of the uterus was entirely preventable. Craniotomy was far preferable to the risk of difficult forceps extraction. No cause had yet been discovered for obstetric shock, and it was usually fatal. Much had recently been said and written about the bad state of obstetric teaching, but the speaker believed that obstetric teaching in this country was never better than it was to-day. The difficulty was in the dearth of obstetric beds for teaching purposes, and in the diminished birth rate.

Dr. L. COLEBROOK said that he thought it was impossible completely to sterilize the vulva. The best antiseptic to use was a watery solution of iodine (2 per cent.), but it must be given at least five minutes to act. In puerperal fever the microbes chiefly responsible were the haemolytic streptococcus, from throat carriers; the anaerobic streptococcus, probably from the intestine via the rectum; and the *B. coli*. Gloves should be washed in water and soaked in a strong antiseptic, such as lysol (2 drachms to 1 pint) or perchloride (1/5,000). Cases of puerperal fever ought to be regarded as emergencies, and sent to hospital in the early stages. Work was at present being carried out on the treatment of these cases by means of the arsenicals.

Reviews

A SURVEY OF RENAL DISEASE

The sixth volume of Mohr and Staehelin's Handbook of Internal Medicine[1] consists of VOLHARD'S "Die doppelseitigen hämatogenen Nierenerkrankungen," now enlarged to thrice its original length, with the addition of a section on surgical diseases of the urinary tract and the male reproductive organs by F. Suter of Basel. Volhard keeps to his former arrangement, commencing with physiology and passing on to such subjects as renal insufficiency, oedema, uraemia, etc., before dealing with classification and the consideration of actual diseases. His classification, now known the world over, remains almost unaltered, and though it has received some criticism there is probably no other which so well fulfils the requirements of clinician and pathologist while still combining completeness with simplicity. An enormous mass of knowledge has been added to the subject of kidney disease during the last twelve years, but as most of the problems—even that of the physiology of the kidney—are still unsolved, this knowledge has not yet had the simplifying effect which comes when theories are proved and hypotheses become facts.

In the preparation of this edition Volhard has accomplished a stupendous task. He gives us not only the most complete survey extant of the modern knowledge, theory, and literature of kidney disease, but, in addition, the benefit of his own teaching and interpretation of the subject. The result is a most valuable contribution to medicine, but essentially a book for the expert rather than for the student or general practitioner. It is gratifying to note, among so much that is, alas, still theory, that there are some real advances towards clarity since the last edition was published. The conception of a "pale" and a "red" type of high blood pressure will commend itself at once to the experienced clinician, and the work of Volhard's clinic on the different mechanisms of the two forms, if confirmed, is a valuable advance. The meaning of renal insufficiency is much clearer than was formerly the case, and the blood-indican and xanthoproteic reactions as tests of renal failure are still too little known and used in this country, especially as the latter can, if necessary, be performed at the bedside. Extrarenal factors, especially in relation to oedema, and the role of the tissues in preserving the constancy of the composition of the blood, are subjects becoming more and more important in the understanding of kidney disease; the sections dealing with these subjects, as also those on compensatory polyuria, on the functions of the glomeruli and tubules, and on the lessons to be learnt from the concentration and dilution test, are particularly clear and satisfying to read. Volhard's conception of ischaemia as the all-important factor in acute nephritis, and of the duration of the ischaemia as the determining factor in the production of the later non-reversible changes in the kidney, is another important lesson in the book, and the doctrine of ischaemia appears again in the explanation of pseudo-uraemic manifestations, the subject of uraemia in general being dealt with in essentially the same way as in the last edition. The survey of the literature appears to be remarkably complete, and is not especially biased towards the works of German authors, though Verney's work on the control of the kidney by the pituitary deserves further mention.

[1] *Handbuch der Inneren Medizin*. Herausgegeben von L. Mohr und R. Staehelin. Zweite Auflage, herausgegeben von G. v. Bergmann und R. Staehelin. Sechster Band. Berlin: J. Springer. 1931. Part I: Pp. xiii + 1023, 93 figures; bound, R.M.48. Part II: Pp. 1024 to 2137, 159 figures; bound, R.M. 99.60.)

It would be futile in a work of this magnitude to pick out one or two points for criticism, and it must suffice to say that the new edition of Volhard's book will retain its place as the world authority on the subject. The section by Suter, on so-called surgical affections of the kidney and genito-urinary tract, is clearly written, and, though not aiming at the completeness of the first part of the book, is sufficiently detailed to serve as a useful source of reference for the physician, for whose purposes presumably it is written. The book is published in the excellent style we have learnt to expect of the best German publishers, and the illustrations, though not over-numerous, are beautifully produced.

VISUAL SENSITIVITY

Much work has been done upon the sensitivity of the eye, both qualitative and quantitative; but it must be admitted that a lack of adequate standardization has detracted considerably from its value. The only true standard which can give results as nearly as possible quantitative and absolute must be based on terms of energy. Many of the classical investigations on vision suffer from this defect; even the well-known sensation curves, for example, upon which so much theorizing has been based, have never yet been determined with a spectrum whose energy equivalents have been accurately measured. In 1925 a very valuable contribution to our knowledge was made by Monroe, whose determinations of the energy values of the minimum chromatic and achromatic stimuli which were appreciable at the fovea were published in monograph form by the American Psychological Association. This excellent work has now a fitting sequel in a similar exhaustive and standardized determination of the sensitivity of the peripheral retina published in the same series.[2] The work was done by Miss WENTWORTH, under the guidance of Dr. Ferree, at the Bryn Mawr College in America.

The research embraces a comprehensive survey of the threshold sensitivity of the retina to light from its centre to the periphery. Spectral lights of a definite composition and purity were used, the quantitative estimations of which were all made in terms of energy. So far as can be judged, a careful control seems to have been made of the many variable factors which tend to introduce themselves in an investigation of this type, and determinations were made both in conditions of light and dark adaptation. It was found that in conditions of light adaptation there was a wide variation of chromatic sensitivity to any given range of wave-lengths from the fovea to the periphery, and that great irregularities occurred in the ratio of the sensitivity of the same colour, or of different colours, at different points in the same quadrant of the visual field, and at corresponding points in different quadrants. This is a fact of importance in the assessment of changes in the colour fields which may have a pathological significance. The conclusion of previous investigators was verified that, given sufficiently high intensities of stimulus, the limits of the visual fields were coextensive with that of white light; and the fact was brought out that the general tendency was for the area of the colour fields to vary with the logarithm of the intensity of the stimulating light. In conditions of dark adaptation the fields for blue and green were limited to 30 or 40 degrees from the fovea. Beyond this limit an increase of intensity in the stimulating light served only to change the achromatic component of the sensation towards white. Yellow, on the other hand, was seen almost to the periphery, and red to the extreme periphery. Within the central area the sensitivity of the dark-adapted eye was found to be far in excess of that of the light-adapted eye. This was already known, but the expression of the difference in terms of energy units is valuable. Moreover, from comparison of the achromatic thresholds of the dark-adapted eye and the chromatic thresholds of the light-adapted eye, it has been possible, for the first time, to evaluate the photochromatic interval on an absolute scale for all kinds of light and for all points on the retina. The definition in precise terms of the first important qualitative change in the reaction of the retina to the intensity of spectral light is of great interest.

The author makes no attempt to relate these results to existing colour theories; but it is evident that until our knowledge of visual sensations is placed upon a quantitative basis by a wide extension of work of this nature, these must always remain essentially of speculative interest.

SURGICAL HANDICRAFT

Though there is always the element of novelty in the perusal of fresh books yet the appeal of new editions of established favourites is often greater, especially when the revision has been as careful as that bestowed upon the tenth edition of *Pye's Surgical Handicraft*,[3] by the late H. W. CARSON. Mr. Carson's untimely death immediately after the work went to press gives, indeed, a special interest to this edition, since it must be regarded as the posthumous contribution of a surgeon of great experience to one of the most generally useful aspects of the art of surgery; for, while not lacking in scientific detail where required, it is particularly to the training of the "surgical artisan" that the book, as its title sufficiently indicates, is directed.

In their preface the publishers draw attention to the fact that "particular care has been taken to avoid sacrificing its individuality," and we are glad to record that this aim has been achieved, for there are many special characteristics of "Pye" which those who are familiar with previous editions would be very sorry to miss, and upon which a good deal of its popularity depended. Not least of these features were the excellent illustrations of Mr. G. Dupuy, which have not only been retained but actually increased in numbers in recent editions. New matter is copious, and includes sections dealing with infected wounds of the hand, where perhaps a reference to the name of Kanavel would not have been inappropriate; the injection treatment of varicose veins; tannic acid treatment of burns; and a brief outline of the uses of radium. The chapter on *x*-ray diagnosis and treatment has been brought thoroughly up to date, and contains some good reproductions of radiograms, which always form a test of the skill of the printer and of the engraver.

The practice of minor surgery varies considerably from school to school, as can easily be seen by comparing the textbooks on the subject from different hospitals. It is not to be expected, therefore, that all the methods described here will find universal acceptance; nevertheless, it can be stated quite confidently that the teaching in *Pye's Surgical Handicraft* is sound in all particulars, and the house-surgeon and practitioner will find it a true vade mecum worthy of their confidence. If some of the most recent innovations in treatment and diagnosis do not find a place in it, we may regard this, not as a sin of omission, but as an evidence of the wisdom of the

[2] *A Quantitative Study of Achromatic and Chromatic Sensitivity from Center to Periphery of the Visual Field.* By Hazel Austin Wentworth. Psychological Monographs, No. 183. Princeton and Albany, N.J.: Psychological Review Company, 1930. (Pp. 192; 50 figures.)

[3] *Pye's Surgical Handicraft.* Edited by H. W. Carson, F.R.C.S. Tenth edition, fully revised. Bristol: J. Wright and Sons, Ltd.; London: Simpkin Marshall, Ltd. 1931. (Pp. xvii + 641; 22 plates, 343 figures. 21s. net.)

editor in refusing to incorporate methods which are frankly in the experimental stage, and which may fail to stand the test of experience—an attitude requiring strength of character in face of the insistent demand for all that is expressed by the term "modern," whether useful or valueless.

INFANT FEEDING

Infant Feeding in General Practice,[4] by Dr. J. V. C. BRAITHWAITE, is outside the common run of books on the same subject. In his preface he draws attention to the difficulty experienced, both by the student and by the general practitioner, in obtaining adequate and scientific instruction in paediatrics, in spite of the fact that the care of children forms a large part of the practice of the family doctor. But he does not assume, as many writers do, that a rule of thumb, easily remembered, is the sole desire of every busy practitioner; he rather chooses to discuss each part of his subject fully before making a recommendation. In the chapter on artificial feeding, for example, he begins with a section on the elementary chemistry of infant nutrition, and this also has a bearing on the later chapter on nutritional disorders. The importance of breast-feeding is stressed in the first chapter, while the second chapter deals with the difficulties which may arise in the course of breast-feeding. The various methods of artificial feeding, with the advantages and disadvantages of each, are discussed in detail, and the last two chapters are devoted to nutritional disorders and to conditions which may simulate them. Appendices include notes on the calorific values of various foodstuffs, a table of milk-mixtures for infants, and a few simple recipes. As Dr. H. C. CAMERON points out in a foreword, the subject is presented, not from the view of the specialist in paediatrics, still less from that of the propagandist in infant welfare, but from that of the general practitioner with special experience writing for general practitioners, and as such the book should make a wide appeal.

SEX AND DISEASE

Dr. R. V. STORER's book on *Sex and Disease*[5] has been written for the purpose of educating the public concerning the dangers of venereal disease. The book is well known in Australia, and has done good work there. For this reason the publishers have decided to issue an edition in England, as they feel that nothing but good can result from a better understanding, by those uneducated in sex matters, of the grave risks incurred through promiscuous sexual intercourse. After having read this book we can confidently recommend it. Dr. Storer, unlike so many who have taken a prominent part in the anti-venereal campaign, has not allowed any emotional bias to affect his judgement of the value of the various methods by means of which venereal disease may be diminished in the community. He lays equal emphasis on education, the provision of facilities for amusement, the raising of moral tone, and on prophylaxis—that is to say, he recognizes that there will always be certain members of society who will find an outlet for their sexual urge, and that for these people education in preventive measures is of paramount importance. We should like to bring this little work to the notice of all who are interested in the venereal question.

NOTES ON BOOKS

DACOSTA'S *Modern Surgery: General and Operative*, first appeared in 1894, and since then it has passed through many reprintings and new editions. The tenth edition,[6] revised by the author with the assistance of Dr. Benjamin Lipshutz, has been published this year. It is a large volume of more than 1,400 pages, with many illustrations. The only section which remains as before is that contributed by Dr. Chevalier Jackson, on direct laryngoscopy, bronchoscopy, oesophagoscopy, and gastroscopy.

We have received a copy of the *Transactions of the British Society for the Study of Orthodontics*[7] for the year 1930. A perusal of its contents shows that the society is steadily accumulating data on the strength of which the vexed question of nature or nurture—heredity or environment—as the chief factor of mal-occlusion, may eventually be settled. In particular, communications by Mr. Charles and by Miss Tildesley show that the members are actively interested in the genetic side of the question. We may add that the second International Orthodontic Congress is being held in London this week. The high scientific level of the 1930 transactions make it certain that the British Society will prove itself worthy of the honour accorded it.

Mate in Two Moves,[8] by BRIAN HARLEY, is a treatise that will appeal to readers who are interested in the subtleties of chess problems, and even to those with a very elementary knowledge of the game. The author illustrates his theme by giving nearly 170 examples, each of which is accompanied by lucid commentary.

PREPARATIONS AND APPLIANCES

A SPIRIT-PROOF ANTRUM PUNCTURE OUTFIT

Mr. ALFRED WALFORD, F.R.C.S. (surgeon in charge of the ear, nose, and throat department, Addenbrooke's Hospital, Cambridge) writes:

The difficulty of sterilization of the maxillary antrum

puncture outfit and paracentesis knives before use has been met by the spirit-proof case, illustrated in the accompanying figure, which Messrs. Allen and Hanburys have made for me.

The antral puncture outfit is the one designed by Mr. Cokeley, and all the instruments are of stainless steel.

British Medical Journal

SATURDAY, JULY 25th, 1931

THE PRESIDENTIAL ADDRESS

It is the ambition of the British Medical Association to represent, and at this moment it does represent, every section of the profession. Each variety of medical work is, indeed, represented within the Association more fully than by the separate societies which have been established outside it. It is no matter for surprise, therefore, that the President now entering upon his office should be a full-time medical officer of health, but it is noteworthy that this should be so for the first time in the history of the Association. Dr. W. G. Willoughby, in the admirable Presidential Address which we have the pleasure of printing to-day, says that too much stress should not be laid on this circumstance because it " tends to obscure the very important fact that preventive medicine has formed from time immemorial an important part of the work of every branch of the profession," and he believes that this will obtain in the future to an even greater degree. His address, appropriately and naturally, deals with " Public health: to-day and to-morrow." He is concerned only incidentally with the triumphs of the past ; but sets out from a somewhat novel aspect the present situation, which, in spite of these triumphs, is still sufficiently disturbing, and discusses the position of the medical profession as a whole in relation thereto.

In regard to the present state of the public health Dr. Willoughby acknowledges that he is a little pessimistic. The various sources of information from which a medical officer of health draws his knowledge ' indicate very clearly how much room there is for improvement.' In the year 1929 about one-third of the total number of deaths occurred before the age of 50. Omitting deaths of infants less than 1 year old, there were more than 40,000 deaths of children under 15 years of age, and more than 20,000 within the next decade of life. The expectation of life is still only 55 years for males and 59 years for females. The tables show almost no change at the ages of adolescence, and at 50 the expectation is increased by about two years only. In the elementary schools the daily absence of children, mainly on the ground of illness, is from 8 to 10 per cent. ; while the percentage found requiring treatment for physical defect, excluding dental defect, has been 20 for each of the past four or five years, and it is not decreasing. Many of the ailments concerned in this may be slight at the time, but they have their effect. Of young adults offering themselves for the Navy, Army, and Air Force there is still a large proportion who have to be rejected on account of some defect, and the only marked improvement compared with the figures of 1910 is in dental condition and chest measurement. Each year about half the insured population comes under treatment by insurance practitioners, and the claims for sickness and disablement benefit have doubled in recent years.

There are factors influencing the future outlook which are not altogether encouraging. The population is becoming increasingly older, and this is due mainly to the decrease in the number of young people, the life of the older generations being prolonged but slightly. Thus, the prospect of further reduction of the death rate becomes less and less. The birth rate is declining, and therefore migration becomes of more importance ; and " on the whole our emigrants are of a better type than our immigrants." The reduction of the birth rate is accompanied by a marked decrease in infant mortality. If the former is differential as against the better elements of the population, and if the latter tends to preserve inferior elements, then the outlook is correspondingly depressing. Fortunately, however, neither of these two suppositions can be held to be proved. Dr. Willoughby seems to assume that there is truth in the former ; but further investigation is required, for we are here dealing with the question of stock, and who can yet say what are the criteria by which babies are to be classified in this regard, or, indeed, which qualities of body, mind, or personality are, in changing circumstances, to be considered the most advantageous for the future of the human, or the British, race? With regard to the latter of the two suppositions, Dr. Willoughby declares himself less pessimistic. " When I am told that nature's way, and the best, is the survival of the fittest infants only, I reply that in too many instances, especially when infantile mortality was higher, the fittest themselves often had no chance of survival. A selection depending on ignorance and neglect is not a natural selection. The diseases which took off these infants removed as many of the fittest as of the weaklings." In any case it will be agreed that " it is essential to take care that in reducing the quantity of our available supply for the future of the race we, at all events, endeavour to preserve the quality of the remainder."

Dr. Willoughby looks mainly to the influence of the medical profession to counteract the less satisfactory features of the public health which have been mentioned. " Medical practitioners, in accordance with their traditions of progress, are taking an increasing interest and a greater part in preventive medicine than at any previous period. Thanks to the work of our Association, the spirit of friendly co-operation between the branches of the profession has steadily grown. . . . There are quite a number of practitioners who, in addition to the preventive work carried on in the course of their own private practices, are giving valuable assistance in the public health service. . . . Though the preventive work of the general practitioner is by no means dependent on any work he may carry out in State clinics, modifications which enable him to take part in the treatment of patients in State clinics are so clearly advantageous that there are signs of this being more developed in future. On the one hand the patients themselves are entitled to the benefit of his varied experience, and on the other hand experience in these clinics would be most valuable to him in his other work.

The clinics would be even more useful if they could be co-ordinated with an increased general practitioner service in the homes; if this could be secured, clinics for treatment would be less necessary." Moreover, in the medical curriculum, public health, which has hitherto been detached from the other subjects, is now being increasingly correlated with all those subjects; and the health education of the public, generally wisely conducted in the elementary schools and by private medical practitioners, though not so wisely by some organized bodies, is having a noticeably good effect. Further, research, both by members of the medical profession and by experts in allied sciences, is resulting in epoch-making discoveries; and, though a large section of the population is not, as yet, getting the advantage of a quick and thorough application of these, Dr. Willoughby believes that "the profession is more and more fitted to provide what is required when the opportunities can be found."

Those who heard the Presidential Address on Tuesday, and those who now read it in our columns, will unite in congratulating the President on having inaugurated his year of office by so interesting, thoughtful, and helpful a pronouncement.

TREATMENT OF MENTAL DISORDER

Regarded alike from the scientific and the social aspect, mental disease sets before us problems as perplexing as any in the whole field of medicine. Intrinsically, by its very nature, disease of the mind offers a barrier to our understanding that might seem well-nigh insurmountable. The scientific study of its many manifestations is none the less being successfully prosecuted from many different angles. It may be hoped that these numerous lines of research will converge in a fundamental discovery. Psycho-analytic inquiry on the one hand, and intensive biochemical and pathological investigations on the other, need not be regarded as mutually exclusive. We prefer to believe that the victory, when it comes, will be a common victory, capable of expression in a common language and in a wider synthesis. The researches of Von Monakow have to some extent pointed the way to this larger formulation. But it is when we abandon the words "mental disease," and instead make use of such terms as "insanity" and "lunacy," that the problem ceases to be merely a scientific one; for here there is the inevitable encroachment on other fields, where conceptions of disorder of the mind have become bound up with obsolete legal enactments and coloured by popular prejudices. From the entanglements so brought about psychiatrists have for long been seeking to be delivered so that their science might find unrestricted scope in its immediate practical application.

The Board of Control, whose report for 1930 has now been published,[1] is the official guardian of the mentally afflicted. Its duties are difficult and delicate, and have been carried out with that rare discrimination whereby legal requirements are interpreted with a refreshing common sense. By the Mental Treatment Act of 1930 the work of the Board has been made at once more onerous and more easy; more onerous in so far as the Act has entailed an enormous increase in the work of the department and a consequent reorganization of, and addition to, the personnel; more easy, or at any rate more satisfying, in that the Board does not now have to struggle against the dead weight of outworn legal requirements, but is able to realize that at last something has been accomplished which ensures the opportunity for early diagnosis and treatment, without hindrance, to every afflicted person. It is for others to see that these opportunities are made full use of. They will not lack the Board's advice and encouragement. Many, but not all, of the possibilities that have been envisaged for the better treatment of the mentally afflicted have become actualities by the Mental Treatment Act. This Act does not accomplish all that might have been accomplished, but, despite that, the Board may well claim that it marks an epoch in the treatment of mental disorders in this country. Inevitably there had to be compromise, and acquiescence in what may be regarded as unnecessary restrictions. Against the privileges of the patients there had to be weighed the rights of the community; and it is not surprising that the balance tilted, perhaps, too often towards the latter. The benefits of the Act cannot be gainsaid; and with proper use further benefits must accrue.

The most important provisions of the Act of 1930 are those which govern the extension of facilities for early treatment. The voluntary patient is no longer excluded from a public mental hospital, whether as a rate-aided or as a private patient; and, what is of even greater importance, he may be admitted into any hospital or nursing home approved by the Board; all of which means, or ought to mean, that the occurrences of suicide in patients, who hitherto had to be certified insane as a prerequisite for treatment, should steadily diminish in number. But the voluntary patient is *ex hypothesi* possessed of volition, and is not the sort that can find congenial company among the chronically insane. The Board has been alive to this special danger and has striven to induce local authorities throughout the country so to adapt their mental hospitals as to ensure proper provision for patients who may be deemed to be sensitive and critical of their surroundings. What visiting committees are urged by the Board to do is to provide a separate admission hospital with ample facilities for classification and separate convalescent villas; and many have done so. This would seem to us to be quite necessary, if future development is to be along the lines of the present Act, as, indeed, it must be. The only other alternative, now no longer possible, would have been a thorough separation of recent cases from chronic cases, not merely an artificial separation in one institution, but in entirely separate institutions; for at present the recent case does mix to some extent with the chronic at the hospital sports, and dances, and cinemas, in the workshops, and in the gardens. Such

[1] Seventeenth Annual Report of the Board of Control, for the Year 1930. Part I. London: H.M. Stationery Office. 1931. (2s. net.)

a scheme, however, it must be admitted, is now impracticable, whereas the provisions of the Mental Treatment Act are both practical and desirable. If all the way is not gone towards a complete division, at any rate all that is humanly possible under present economic conditions has been effected, and it is for the local authorities to follow the Board's lead in this matter.

For incipient mental illness, out-patient treatment is of the utmost value. The Board is already gratified by the development of out-patient clinics, and notes with satisfaction that where a clinic is held at a voluntary hospital there is a general willingness to associate with it the superintendent of the mental hospital, and to appoint him on the honorary staff. The Board views this as most desirable, and hopes that local authorities will reciprocate by making the honorary staff of the voluntary hospital the consultants at the mental hospital. It attaches particular importance to such reciprocal arrangements with teaching hospitals from the point of view of medical education; and with this statement of the Board we are in entire concurrence. If mental illness is to be recognized early it is imperative that general practitioners should have had as students ample opportunities for the study of such disorders. By the new code for the reception of "temporary patients" it has become possible to treat, without certification, patients who are incapable of expressing willingness or unwillingness to receive treatment—such cases as are classically represented by the acute toxic confusional states. Hitherto these patients could only be detained under treatment after certification. The scheduled precautions may seem unnecessary, but certification can at any rate be avoided if practitioners will see to it that such patients are dealt with under the Mental Treatment Act and not by the old procedure.

A considerable time must necessarily elapse before the Board of Control can gauge the full effect of these changes in our law. The painstaking preparations which were made to ensure the success of the new Act have been amply rewarded by its smooth and effective operation; and there is every indication that its provisions will be increasingly made use of to the benefit of the whole community.

BIOLOGICAL STANDARDIZATION OF DIGITALIS

The introduction into the *British Pharmacopoeia* of biological tests for the activity of digitalis preparations is a reform long overdue. As a matter of fact, the leading drug houses have practised such standardization for more than twenty years, and therefore the medical profession has been able to obtain reliable preparations. The official pharmacopoeial regulations have, however, furnished no safeguard against the sale of inactive preparations of digitalis, and in practice wide variations in activity have been demonstrated. We are pleased to learn from the report just issued by the General Medical Council (Report No. 4 by the Subcommittee on Digitalis and Strophanthus)[1] that this omission is to be remedied in the new *Pharmacopoeia*. This report contains recommendations on the methods of biological standardization to be adopted for these drugs. In the case of digitalis, an international standard powder has been recognized in Germany since 1928, as well as an international unit of dosage, which is equivalent to the specific activity contained in 0.1 gram of the international standard powder. In Germany manufacturers are required to make preparations from digitalis leaves which do not differ in activity from the standard powder by more than 15 per cent. This rule discourages the production of digitalis leaf of more than an average activity; therefore the English subcommittee has made regulations which aim at avoiding the necessity for dilution. The regulations are somewhat complex, because they are required to suit not only the wholesale manufacturers but also the pharmacist who desires to make up his own preparations. Digitalis leaf must be standardized biologically by comparison with a standard preparation (except leaves to be used for making tinctures, which will be standardized before issue). After standardization the manufacturer can, if he wishes, adjust the potency of the leaf by admixture with other leaves so as to bring it to the standard strength of 10 units per gram. Alternatively, the leaf may be made directly into tablets or pills, and the contents of the preparation described in terms of units of activity. Tincture of digitalis may be prepared in two ways: (*a*) from unstandardized digitalis leaf by the percolation process, when the final volume of the tincture is adjusted in accordance with the result of a biological test; (*b*) from previously standardized digitalis leaf by the percolation process, without carrying out a biological test on the percolate. With regard to the biological assay of digitalis, the methods recognized are those depending upon the lethal dose for frogs or upon the intravenous dose required to arrest the heart beat of either a cat or a guinea-pig. The effects produced on a series of animals by the preparation under test are compared with the effects produced by the standard preparation in a parallel series of experiments. The International Conference at Geneva recommended the use of crystalline ouabain as a standard for preparations of strophanthus. The subcommittee, however, recommends the adoption of a standard tincture of strophanthus. It has laid down details for the standardization of tincture of strophanthus and of strophanthin. The devising of biological tests that can serve as presumptive legal standards is a matter of much difficulty, and the subcommittee is to be congratulated on the care and skill that it has shown.

THE LIMITATION OF MANUFACTURE OF DANGEROUS DRUGS

The conference on the limitation of the manufacture of narcotic drugs, to which reference was made in these columns on June 27th (p. 1125), concluded its labours on July 13th by the signature of a new International Convention intended to implement The Hague Opium Convention of 1912 and that of Geneva of 1925. As this new Convention is not to become operative unless and until it shall have been ratified by twenty-five nations, of whom four must be manufacturing countries, it may be reasonably concluded that the international control of the commerce in dangerous drugs will, for some considerable period, be regulated by the provisions of The Hague and Geneva Conventions. A

scheme for the allocation of fixed quotas of production among the eight manufacturing countries, though advocated by the League of Nations Advisory Committee, by the London Conference of last year, and by the British delegate, was finally rejected. The new Convention applies to codeine and dionin, as well as to morphine, heroin, cocaine, peronin, and their preparations. Largely owing to the British representations the prohibition of the manufacture of heroin, as already effected in the United States, was not approved of, but it was agreed that exports of that alkaloid should be consigned only to Governments. Moreover, any new product from opium or coca leaves is not to be exported until the Health Committee of the League of Nations has decided whether or not such drugs may lead to addiction. The reports so far available of the articles of the new Convention state that they will allow each manufacturing nation to obtain trade where it can, but each is to undertake not to manufacture in excess of the annual estimates of the amounts required. Such estimates are to have regard to home requirements, to certificated exports, to Government stocks, and to what is needed for conversion into other products. Any excess in one year is to be deducted from the next year's estimate. It is not clear on the face of it how this complicated procedure, if and when ratification by twenty-five nations shall have been achieved, will effect any advance on the methods hitherto devised under The Hague and Geneva Conventions of 1912 and 1925. The putting of those Conventions into force by Great Britain under the Dangerous Drugs Acts, 1920–25, appears, according to the League of Nations' "Analysis" (*British Medical Journal*, July 18th, p. 107), to have reduced the amounts of morphine, heroin, and cocaine "unaccounted for" to negligible proportions. If all the producing countries had ratified and carried out the Conventions of 1912 and 1925 in the same way as Great Britain the desired suppression of illicit traffic might have been more effectively realized.

COMPULSORY VACCINATION

On July 16th the Minister of Health received a deputation of Members of Parliament on the question of the abolition of compulsory vaccination. Mr. Leach, M.P., said that the views of the deputation were set out in a memorandum, of which a copy had been sent to the Minister. Their sole object was to secure that compulsory vaccination should be abolished, and they hoped that the Government would be willing to introduce, or give facilities for, the necessary legislation. They believed that all they wanted could be achieved by a one-clause Bill. The Minister said, in reply, that he had read the memorandum submitted to him. It contained a number of statements with which he must not be taken to be in agreement, but he thought it was unnecessary for him, on the present occasion, to discuss the merits of statutory vaccination. His position was that he was bound, as Minister of Health, to administer the law as it stood. The effect of the Local Government Act had been to place the administration of the Vaccination Acts in the hands of the larger local authorities, and he did not contemplate any drastic amendment of the law until those authorities had had time to gain experience of the operation of the Acts in force and furnish him with their views and advice. He could not admit that the object which the deputation had in view could be achieved by a one-clause Bill. On the contrary, he believed that complicated and highly controversial legislation would be necessary to secure what the deputation desired. In view of the many commitments of the Government and of the great pressure on parliamentary time, he was bound, in present circumstances, to prefer the claims of other more urgently needed legislation to those of a Vaccination Bill. While, therefore, he could have no objection to the introduction of a private member's Bill as a means of testing public opinion, he could give no assurances—which would in any case require Cabinet authority—either of support for such a Bill or of the introduction at an early date of Government legislation.

THE CANCER CAMPAIGN IN AUSTRALIA

Steady advance in the process of co-ordinating various lines of investigation, in the better organization of treatment, and in the diffusion of information about recent work is reported in the May issue of the *Journal of the Cancer Research Committee of the University of Sydney*. This quarterly publication is distributed to every medical practitioner in the Commonwealth. It has now been decided that, while the University will continue to concern itself primarily with the direction of cancer research, and will retain some association with the actual arrangements made for treatment, the hospitals should now be able to relieve it of a certain amount of the responsibility of providing facilities for patients. The administrative problems arising out of this decision are receiving careful consideration. A well-attended post-graduate course in radiotherapy for general practitioners was held in 1930, and the University is contemplating the institution of a diploma in radiology. Aided by the Cancer Fund of Sydney University, to which many references have been made in these columns, nine research workers have been continuously engaged in the attempt to elucidate various cancer problems, one of these being an investigation of the activities of radiations of different wave-lengths. The professor of pathology is making a preliminary examination of the large collection of material and records which have been accumulating at the Royal Prince Alfred Hospital, with special reference to the radio-sensitivity of malignant and other tumours. This issue of the *Journal of the Cancer Research Committee* includes a practical article on the problem of the "erythema dose," by Drs. A. T. Nisbet and Leila Keatinge, who point out that this rather vague term has as yet no standard value, its implications being modified by different conditions of filtration, voltage, the area of skin infiltrated, the thickness and density of the tissues, the method of dosage, and the distance of the anti-cathode from the skin. The authors indicate in this connexion a possible definition of certain degrees of erythema which appear to be capable of being standardized. In March, 1930, the first Canberra Cancer Conference was held, dealing largely with radium; a second conference followed twelve months later. A short report is published of this second meeting, at which the opinion was expressed that the further development of consultative clinics must include some reliable system for following up patients after treatment. The lines of progress of cancer research in Australia are depicted generally in an article by Mr. H. G. Chapman, who

describes briefly what is being attempted in various centres, and the degree of success achieved so far in each. By means of this university periodical, research workers are kept in touch with each other, and the general practitioner receives at regular intervals practical information about the progress that is being made.

POST-GRADUATE WORK IN VIENNA

The American Medical Association of Vienna, which was founded in 1904, and is a society of English-speaking medical practitioners, publishes a useful "blue book" every two years. The new edition of this, which has recently appeared, contains a comprehensive list of the study courses available in Vienna throughout the year for those who have little or no knowledge of German. The society has arranged with prominent physicians and specialists of the University of Vienna to conduct special courses and provide private tuition as may be required, and on reasonable terms. About 4,000 medical practitioners have become registered members of the association since January, 1923; a quarter of these joined it last year, an indication of the rapid growth which is going on. Any medical practitioner arriving in Vienna as a total stranger, even though unacquainted with the German language, can, through its agency, obtain specialist instruction in any subject for periods of any length. *Ars Medici*, the official monthly bulletin of the American Medical Association of Vienna, contains reviews and abstracts of the latest publications in foreign medical literature, special departments being devoted to German and Austrian medical research; a special section deals with the scientific and social activities in Vienna. Inquiries may be addressed to the secretary of the American Medical Association of Vienna at its headquarters, Alserstrasse 9, Vienna VIII.

ANNUAL MEETING NOTES

"THE BOOK OF EASTBOURNE"

All members attending the ninety-ninth Annual Meeting of the British Medical Association at Eastbourne this week have received a copy of *The Book of Eastbourne*, written for the occasion, and edited by the Rev. W. Budgen, M.A., F.S.A. It is an interesting and very well-produced volume, worthy of a place beside the attractive books issued in connexion with recent meetings of the Association. Indeed, the executive authorities are altogether too modest about it in their foreword, though they pay a well-deserved tribute to the Editor, who not only enlisted the help of experts on various subjects concerning the locality, but also wrote several of the articles on Eastbourne and its neighbourhood in times past and to-day. In the opening chapter Eastbourne is epigrammatically described as a modern town of ancient lineage: "The rapid growth in recent years of this highly favoured watering-place has given an impression that it is entirely a modern creation, without history and of no consequence in days gone by. This is quite contrary to the facts." A large part of the rest of the book provides convincing evidence in rebuttal of the popular view. Sir Arthur Smith Woodward (who co-operated in the discovery and interpretation of the Piltdown skull) writes on the geology of the district, and Mr. E. Cecil Curwen on the prehistory of the Eastbourne Downland. Mr. Walter H. Godfrey contributes two chapters of historical interest, one on Lewes, the county town, and the other on mediaeval hospitals, with special reference to those in the county of Sussex. Mr. John E. Ray writes on Pevensey and Battle, and Mr. Budgen on ecclesiastical history and on the villages near Eastbourne, while Mr. Ernest Straker gives an account of the Sussex iron industry, which was for three centuries the most important trade in the county. The flora and avi-fauna of the Eastbourne district are described by the Rev. A. A. Evans, and there is an unsigned note on Eastbourne as a centre of education, which recalls the saying that there are 365 schools in that town, one for each day of the year. The President, Dr. W. G. Willoughby, whose portrait forms the frontispiece, writes with full knowledge and authority on the natural and social conditions of Eastbourne, with a brief account of the local hospitals, which were described by him in more detail in our issue of April 11th. *The Book of Eastbourne* is printed in beautifully clear type, the many illustrations are excellently reproduced, and (to round off a thoroughly workmanlike production) there is a full index. Everyone who takes part in the Annual Meeting will value this book as a memento, and feel grateful to Mr. Budgen and his accomplished fellow contributors.

ANNUAL REPRESENTATIVE MEETING

Friday, July 17th

It was fitting that the first session of the Representative Meeting in the Town Hall at Eastbourne should be marked by a tribute to the personality and work of one whose absence, after so many years' service to his profession and the community, could not but cast a shadow over the opening proceedings. The Representative Body honoured the memory of E. B. Turner, and expressed its sympathy with his wife and family with a deep and abiding sense of personal loss. Before turning to the business of the day, the Chairman extended the welcome of the meeting to an unusually large number of new representatives, over seventy of whom shared its deliberations for the first time. Amongst old friends a very special welcome was accorded to Dr. R. H. Todd, "the representative of Australia." Our full report of the first two days' proceedings is published in the *Supplement* this week.

Adoption of the standing orders was followed by a brisk discussion on the methods of reservation of seats, which resulted in a victory for those who hope to discount the drawbacks of late arrival at the place of meeting by early rising on the morning of the first day. Next year at least there will be no advance reservation of seats. This was followed by the election of Lord Dawson as President of the Association for the year of its centenary, and the welcome as a Vice-President of Professor Burgess, who, in the unavoidable absence of Professor Harvey Smith, has been Acting President during the past year. The preliminary proceedings were concluded by an enthusiastic reception of the Chairman of Council's reference to the award of the Gold Medal of the Association to the Treasurer and the Medical Secretary, and the meeting passed to its main business in a discussion, opened by Dr. B. H. Pain with characteristic vigour and lucidity, on the method to be adopted in the promulgation of the Association's policy, centrally and locally. The motion which Dr. Pain introduced dealt specifically with schemes for maternity service, but the general principles formulated by the Chairman of Council in the course of the debate are of far wider application, and it is important that they should not be overlooked in determining the appropriate functions of the central and local organization of the Association.

In his presentation of the Financial Report Mr. Bishop Harman may claim an unusual triumph, since he escaped most of the customary criticism. Mr. Waterfield's question as to the proportion of the Association's resources directly devoted to the promotion of scientific research and medical

education elicited a striking statement, which deserves detailed study. On the Organization Report the Council's proposal for the creation of a class of Foreign Corresponding Members received cordial approval. The absence of controversial business left time for an interesting analysis of the composition of the profession, which Dr. Morton Mackenzie introduced with a well-deserved tribute to the card index department at the head office. It is to be hoped that Mr. Souttar's reminder, on the Science Report, that the individual may best help research by engaging in it personally, and his explanation of the meaning of the time limit suggested in connexion with the collective investigation on cancer, may be productive of more effective support than has yet been forthcoming for this important undertaking of the Association.

Dr. Lyndon, whose return to active duty was warmly welcomed by the meeting, had no easy task in presenting the Council's recommendation in connexion with the ethics of patenting inventions and discoveries in the medical field. The discussion which followed his explanation marked a real advance since last year in the general appreciation of the difficulties to be met, and a healthy desire to explore all relevant facts before deciding upon the best method of applying the traditional standards of the profession to the increasing complexities of international economic conditions. It showed also that for the moment there remain real differences of opinion within the profession, and perhaps some slight misgivings as to the wider implications of one speaker's impassioned sentiment against having any sentiment at all in professional matters. The amendment finally adopted, on the motion of Sir Robert Bolam and Dr. Bone, has the merit of reasserting traditional values, without unduly restricting legitimate development of new methods of work pending the production of a comprehensive and definite statement of policy on an extremely difficult point. The Journal Report elicited a warm expression of appreciation of the improvements in typography and in the reproduction of photographs, effected under conditions of considerable difficulty during the past year. It was followed by the Medico-Political Report, on which Dr. Bone found himself in the unusual position of having only two minor recommendations to put forward, on both of which he was not unwilling to accept modifications suggested by the Divisions. The subsequent debate on the vexed question of methods of collecting fees for attendance on road accidents was distinguished by the ingenious contribution offered by Dr. Pain on behalf of Kent, an effective speech by Dr. Nash suggesting the possible contribution of the public health service in this connexion, and an interesting review of the manner in which the question has been dealt with locally so far as police calls are concerned.

Saturday, July 18th

The agenda for Saturday suggested at the outset a day of small things, and the Representative Body was in fact largely employed in dealing with points of detail. Issues of far-reaching importance were, however, raised in general discussion on each of the four reports which fell to be considered. On the National Health Insurance Report such a discussion was opened with characteristic fervour by the member for Banff in connexion with the regulations restricting the opportunities of insured persons to exercise the right of free choice of doctor, and resulted in an emphatic protest, the importance of which was rightly stressed by Dr. Brackenbury, against the imposition of such restrictions. Perhaps not the least significant feature of the debate was Dr. Dain's incisive comment upon the allocation of responsibility for some at least of the present difficulties in connexion with certification. The Council's recommendations for the representation of Northern Ireland on the Insurance Acts Committee and with reference to the administration of additional benefits were accepted as a matter of course, and the meeting warmly endorsed the protest of Newcastle-on-Tyne against the official sanction of the system of offering gifts as an inducement to the presentation of prescriptions by insured persons. The impression left by the discussion of the report on ophthalmic services was that the urgency of the need for an economically practicable means of supplying qualified ophthalmic services to the insured population is in no way diminished; that the Ophthalmic Treatment Board has made sound progress in this direction during the past twelve months; and that the criticisms of the scheme came in the main from those areas where it was not yet fully established. The recommendation deprecating the instruction of opticians in clinical ophthalmology was accepted without serious question, and in a definitely improved form.

No recommendations were submitted by the Council on the Public Health Report, but the motions of Divisions raised issues of fundamental importance, those from St. Pancras and East Norfolk threatening the integrity of the agreed scale of public health salaries, those from Brighton challenging the constitutional validity of an important part of the operative policy of the Association. The danger was averted at the outset by the ruling of the Chairman on the point of order involved. That this was achieved without the loss of a useful discussion on the possibility of improving the constitutional provision for determining the policy of the Association was largely due to the statesmanlike manner in which Dr. Hawthorne handled a somewhat awkward point. The motion from Bournemouth on the development of health services under the Local Government Act occasioned an informative review of the progress actually made in different parts of the country, and the manner in which the Association has contributed to that progress.

On the Hospitals Report the preliminary discussion on the remuneration of visiting staffs of voluntary hospitals for the treatment of State-maintained and rate-maintained in-patients showed that the policy which some Divisions sought to stigmatize as impracticable was already working successfully elsewhere. In presenting the Report on the Problem of the Out-patient the chairman of the Hospitals Committee took the unusual course of asking leave to adopt at the outset the rearrangements proposed by Hendon, Marylebone, and Liverpool. The reception of the request lent some colour to a suspicion that not all the representatives had made that preliminary survey of the documents before them which would have removed any doubt as to the scope and effect of those amendments. The rejection of his proposal to refer the report back for further consideration can hardly have come as a surprise to Sir Ernest Graham-Little, who described his motion as a forlorn hope. The vote left no doubt as to the confidence of the meeting in the capacity of the Hospitals Committee of the Association to arrive at a fair estimate of the actual conditions of hospital practice, or its verdict on the merits of the policy presented for its consideration.

Monday, July 20th

Monday morning had been allocated in advance to the discussion of medical charities and the work of the Overseas Branches and Divisions. Full justice was done by Dr. Douglas, in his eloquent appeal, to the urgency of the call for more general, more sustained, and more generous support for the charities; to the memory and example of the pioneers to whom we owe the existing provision for relief of distress in the profession; and to the work actually done by the British Medical Association, centrally and locally, during the past year. If the problems of medical benevolence were to be solved by unfettered debate, the outlook for next year would be

bright indeed, for there was much "talk about it and about," and Sir Robert Bolam had some justification for his remark at one stage of the discussion that if he had arisen betimes to every point of order, he would have had little rest during its progress. From the purely financial point of view the amount required to meet the position is insignificant, and such corporate study of its implications should do something towards removing what has been a standing reproach to the profession for far too long.

On the reports of the work of the Dominions Committee and the Oversea Branches the meeting had the usual opportunity of making the acquaintance of the oversea representatives. Distinguishing features of the discussion were the Chairman's tribute to the example of successful organization offered by the Gibraltar Branch; Mr. Mill's account of the part played by the Association in the disastrous earthquake in New Zealand early this year, and his appreciation of the sympathy and help offered by the parent body; and Dr. R. H. Todd's practical suggestion for improving the service offered to the Oversea Branches by the Central Office.

The debate on the Hospital Report, resumed on Monday afternoon, by no means reached the usual standard of the Representative Body. It left the impression that the meeting was mainly concerned with what Dr. Dain (in a moment of pardonable exasperation) described as doing drafting work and doing it very badly. This was due in part to diversities of opinion on the platform and a consequent failure of the help usually available from that quarter. But tedious as it sometimes seemed, the debate was not without its uses, for the Hospital Policy of the Association is primarily an instrument of education, and as such it must fail, unless it is put forward at every stage by persons fully seized of its implications. Time given to the elucidation of even minor points is therefore not wasted. In the event, the Council was left free to proceed with its programme in respect of out-patient departments and schemes for providing consultant services for "contributory" patients—a result which owed much to the timely help given by Sir Robert Bolam. For the rest the meeting emphatically refused to express any opinion upon the material or ethical aspects of sweepstakes as a method of financing voluntary hospitals, satisfied, perhaps, with the earlier discussion upon the motion from Torquay.

A motion from Brighton, designed to prevent encroachments on private practice in the sphere of "mental illness," produced one of the very few close and informative debates which took place during this year's meeting. A comprehensive series of motions by Kensington was presented by Mr. Stratford, and received by Dr. Dain as a happy augury of the part to be played by Kensington in the near future in the development of National Health Insurance services. Most of the motions from individual Divisions were, with the consent of the meeting, referred to the Council, but that on the charges levelled at the profession in connexion with increased sickness certification under the Insurance Acts elicited a statement of substantial value from Dr. Dain.

It was a happy conjunction by which, when the moment came for Dr. Hawthorne to relinquish the high office in which he has rendered such devoted and distinguished service to the Representative Body for an extended period, the thanks and appreciation of the meeting were voiced by one of the first women representatives sent by an Oversea Branch—a relatively junior member of the Representative Body whose energy has been conspicuous throughout the meeting—and by one of Dr. Hawthorne's predecessors in the chair.

LUNCHEON TO REPRESENTATIVES FROM OVER-SEAS

On the first day of the Annual Representative Meeting the representatives from over-seas were entertained at luncheon at the Cavendish Hotel, Eastbourne. Dr. C. O. Hawthorne occupied the chair, and gave a welcome to the guests. He said that it was fully appreciated what the journey must have meant to many of those present in time, trouble, and expense. Those at home desired to cultivate their personal acquaintance, and to hear of the activities, and, if such there were, of the difficulties of the Branches from which they came. The guests would be particularly welcome on the platform of the Representative Meeting when the work of the Oversea Branches came forward for discussion, and he hoped that when they returned they would bear with them a message of good will and greeting to their comrades. The British Medical Association, Dr. Hawthorne continued, had an imperial range and interest, though it was not concerned with any of the contentious questions which disturbed and agitated imperial politics and economics. This year, owing to the fact that the meeting lay between the visit to Canada of 1930 and the Centenary Meeting of 1932, the number of oversea guests was rather smaller than usual, but, if fewer, the welcome which was extended to them was no less cordial. It was hoped during the Centenary Meeting to have a special meeting for discussion of some topic in which all the Branches, home and oversea, had a common interest, and possibly some suggestion might be forthcoming on the present occasion which would result in a fruitful conference next year. Three very brief responses were made on the part of the oversea guests. One was by Mr. T. Mill of the Canterbury (New Zealand) Division, who said that in his Dominion at least the value of the British Medical Association was thoroughly understood, because practically every member of the profession there was in the fold of the Association. It was the furthest away of the Dominions geographically, but spiritually perhaps the nearest. The second response was from Dr. D. H. Wessels of Capetown, who spoke of the excellent results of the visit of the Medical Secretary to South Africa. Large accessions of membership had taken place there, and during the last session a very creditable Medical Act had been placed upon the Statute Book. Dr. W. Anstey Giles of the South Australian Branch, who also responded, claimed to be the oldest member of the Association present, having joined in 1883. He spoke of the pleasure and benefit he had derived from meetings of the Association in South Australia, and also of the value derived from the visits of the late Dr. J. A. Macdonald, Sir Ewen Maclean, and of other visitors from headquarters. Time did not permit of further speech-making, but the names of the oversea guests present were read by Dr. Anderson. They included, in addition to those mentioned, the following:

Lieut.-Colonel G. T. Burke (United Provinces), Lieut.-Colonel R. E. Wright (South Indian and Madras), Major C. Crawford Jones (Grenada), Dr. J. W. Adams (Border Branch, South Africa, East London Division), Dr. D. P. Williams (Assam Valley), Dr. G. Waugh Scott (Malayan), Dr. H. B. Van der Merwe (Pretoria), Dr. W. R. Fea (South Canterbury, New Zealand), Dr. W. Dunlop (Mesopotamia), Dr. R. H. Todd (New South Wales), Dr. J. A. Doctor (Wellington, New Zealand), Dr. J. Hutson (Barbados), Dr. S. Burfoot (Punjab), Dr. Theodora Easterfield (Poverty Bay, New Zealand), Dr. J. B. D. Galbraith (Victorian), Dr. J. D. Reynolds (Uganda), Dr. A. G. Coia (British Guiana), Dr. H. Ludovici (Ceylon), Mr. H. J. Eizenberg (Queensland), Dr. Agnes Bennett (Palmerston North, New Zealand), Dr. B. Spearman (Zanzibar), and Dr. L. D. Lennard (Uganda).

HAMILTON BAILEY: COMPLETE ERADICATION OF THE THYROGLOSSAL TRACT

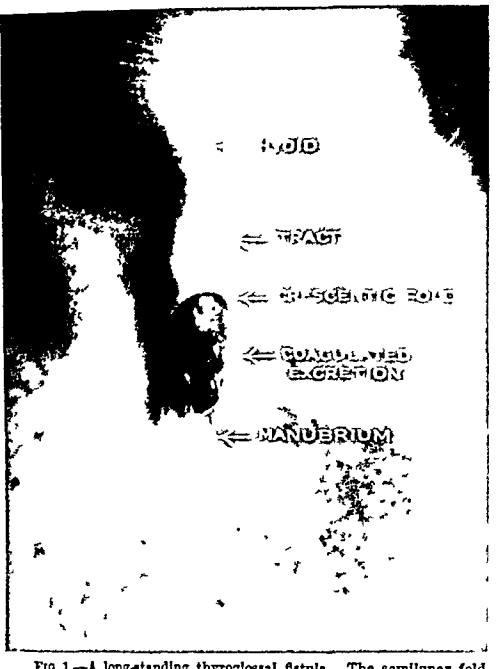

FIG 1.—A long-standing thyroglossal fistula. The semilunar fold is characteristic

FIG 2.—Lateral radiogram after an injection of lipiodol into a thyroglossal fistula. The tract passes up to the foramen cæcum. (Radiogram by Dr. H. N. Crowe, Worcester.)

R. H. McKEAG: PREVENTABLE DENTAL DEFORMITIES

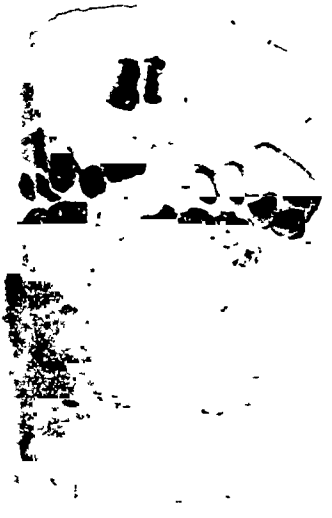

FIG 1.—Results of adenoids. Note narrow crowded arches, protruding upper incisors, corners for food to collect in which the tongue cannot clean. This patient has a receding chin and a vacant perpetual grin.

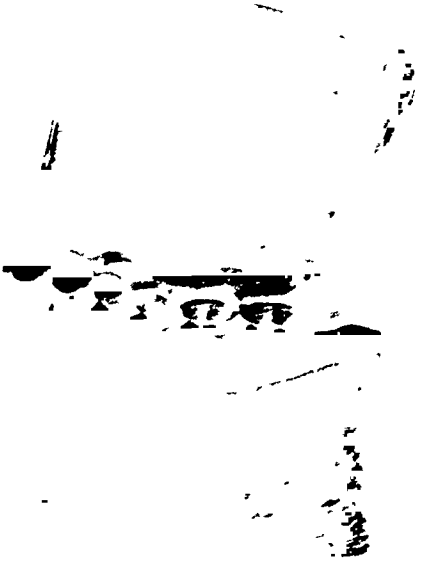

FIG 2.—Result of thumb-sucking. Note protruding front teeth. The appearance of an otherwise good looking girl is entirely spoilt by this deformity

FIG. 3.—Result of lip-biting and tongue-biting. Note protruding upper left central due to lip-biting, and complete loss of articulation on the left side, due to keeping the tongue between the teeth.

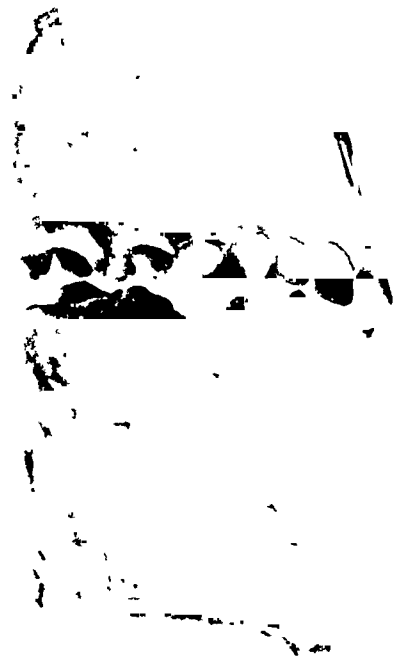

FIG. 4.—Same as Fig. 3, showing the normal articulation on the right side. The patient has acquired considerable mobility of the lower jaw and can bite on both sides, though not using both together.

FIG. 5.—Result of premature loss of deciduous teeth. Note extreme crowding of teeth. The lower front teeth have fallen back and have grown too long in trying to reach the upper teeth; instead of biting on the upper teeth they bite on the mucous membrane of the roof of the mouth.

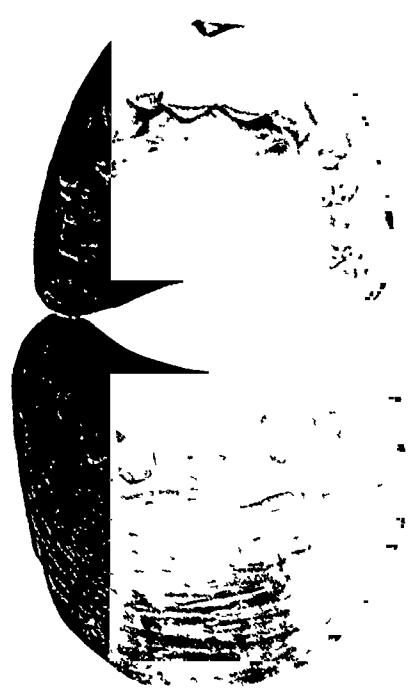

FIG. 6.—Same as Fig. 5. Note lack of growth of upper alveolus. The gum in the front of the lower jaw is very inflamed and the teeth are coated around their necks with tartar.

FIG. 1.—Radiogram taken November 3rd, 1930, showing separation of the epiphysis of the femur and upward displacement of the trochanter.

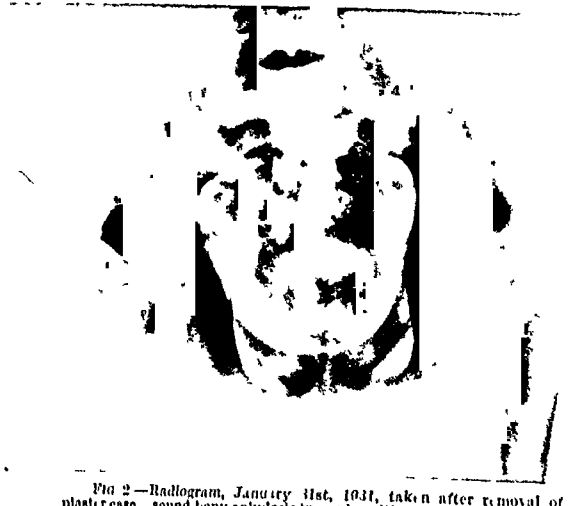

FIG 2.—Radiogram, January 31st, 1931, taken after removal of plaster case, sound bony ankylosis in good position.

FIG. 1.—Cross section of medulla just below pons (Case 1).

FIG. 2.—Tumour of the kidney (Case 1).

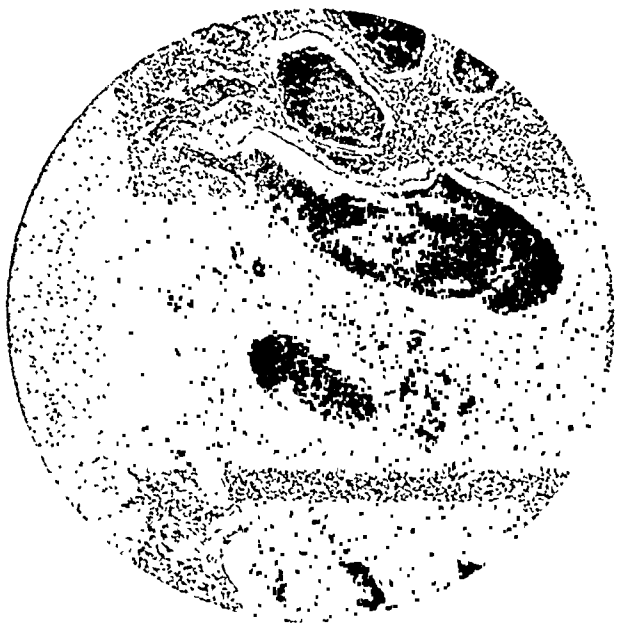

FIG. 3.—Tumour of the medulla × 47 (Case 1).

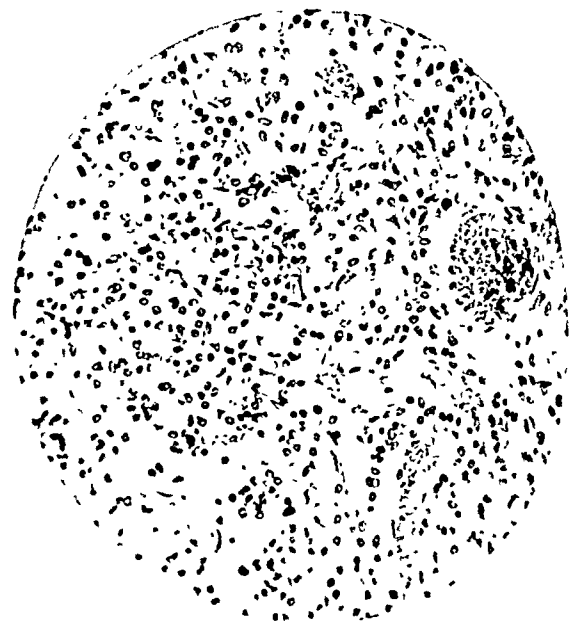

FIG. 4.—Tumour of the medulla × 300 (Case 1).

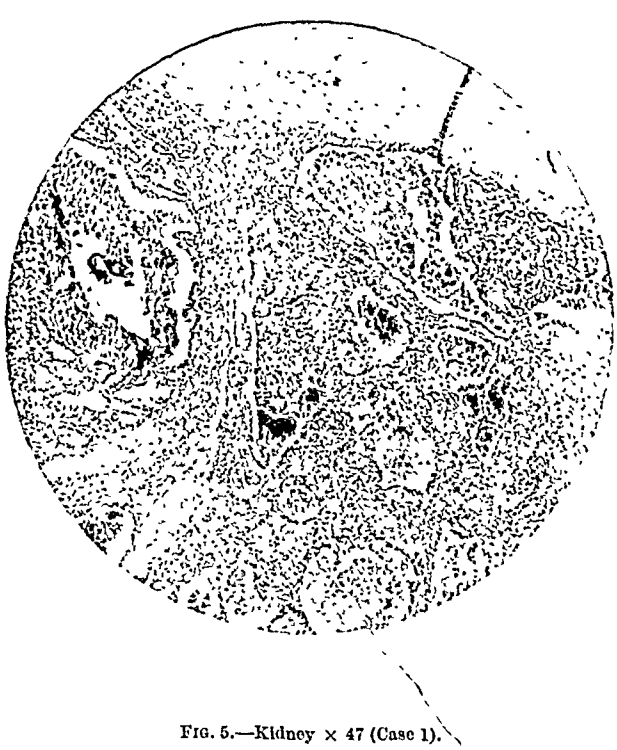

FIG. 5.—Kidney × 47 (Case 1).

FIG. 6.—Kidney × 300 (Case 1).

IMPERIAL SOCIAL HYGIENE CONGRESS

THE VENEREAL DISEASES PROBLEM THROUGHOUT THE EMPIRE

An Imperial Social Hygiene Congress, organized by the British Social Hygiene Council, was held at the British Medical Association House, Tavistock Square, from July 13th to 17th. At the opening session, which was presided over by Sir BASIL BLACKETT, and afterwards by Mr L. S. AMERY, M.P., an address of welcome to the delegates from associations in the Dominions and Colonies was delivered by Lord PASSFIELD, Secretary of State for the Colonies, who expressed the view that in venereal diseases, as in others, science had gone ahead of administration. The discovery of radical methods of treating syphilis by injecting arsenical compounds, he said, was one of the greatest discoveries in modern medicine, but administration, which included the education of public opinion on the subject, had not yet taken the fullest advantage of the facilities which science had made available.

The remainder of the first day of the congress was devoted to short addresses by speakers from all parts of the Empire who described the present position in respect to venereal diseases, the administrative measures for treatment and prevention, and the reaction of public opinion. Particular interest attached to the account of administrative measures in New Zealand, where the Government has wide powers, the Department of Health being authorized to order to hospital any infected person, and to institute legal proceedings against any who failed to take proper precautions against the spread of his infection.

At the second session, over which Surgeon Rear-Admiral R. St. G. S. BOND presided, the problem as it affects the defence forces and the mercantile marine was discussed. Surgeon Commander R. J. G. PARNELL referred to the decreasing prevalence of venereal diseases in the Navy. The average number of cases for the three years 1911–13 was 12,646, as compared with 6,258 for the three years 1927–29, and the annual average of days lost to the Service during the former period was 273,179, as compared with 139,070 during the latter. His personal view was that prevention was primarily a matter of education. The position of affairs in the mercantile marine was put forward by Dr. A. O. ROSS (venereal diseases officer, City and Port of Liverpool), who pointed out that there were in that Service approximately 170,000 men, who, by reason of their calling, were exposed to almost constant sexual temptation, and there was no single authority like the Admiralty to issue regulations with a view to uniformity and discipline.

THE CHOICE OF REMEDIES IN SYPHILIS

Colonel L. W. HARRISON opened a discussion on this subject in the medical conference. The choice of remedies, he said, was probably more important in the early stages than in the late; in the early stages he considered that the thing to do was to concentrate on the eradication of the disease out of hand. Of the arsenobenzene compounds he gave first place to the original '606'. He believed that it hit the spirochaete harder and longer than did '914' in a dosage which was equivalent in terms of arsenic. Unfortunately, the use of '606' was attended by inconveniences in the form of reaction which would deter many patients from continuing attendance, and he thought that the better results it would achieve in the individuals who persevered would be more than counterbalanced by the defaulting of others which the immediate reactions would produce. Of the other preparations he thought that the sulpharsenobenzene class, given deep subcutaneously, acted better than '914' given intravenously, but they often caused sufficient pain to defer the clinic patient from attendance. The tendency in his own clinic was to use more '914,' though in private cases he used more sulpharsenobenzene than '914.' Another disadvantage of sulpharsenobenzene was that it seemed to cause more aplastic anaemia. He believed that approximately equal results were to be expected from equivalent doses of '914' or stabilarsan given intravenously, and of sulpharsenobenzene given deep subcutaneously, or from silver salvarsan intravenously in half these doses, consequently one would use the preparation which appeared most convenient in the circumstances, reserving others for use as changes in subsequent courses where the patient had not responded to the first course so well as the average. In speaking of bismuth, Colonel Harrison mentioned that at St. Thomas's clinic a series of cases were being treated with cardyl in conjunction with '914,' and he hoped in due course to be able to compare the results with those of treatment with bismuth oxychloride in conjunction with the same amount of the arsenical preparation. With regard to the place of mercury in the therapy of early syphilis, the antisyphilitic effects of mercury were proportional to the mercurial ions concentrated in the tissues. In the majority of cases one was brought up short of one's goal by the patient's intolerance of the necessary dose. The administration of mercury by the mouth in early cases should only be adopted when circumstances prevented the use of other routes. The choice of insoluble preparations was between calomel, mercury in fine subdivisions, and the salicylate. Of these from the therapeutic point of view, calomel, on account of the regularity of its absorption and its activity, was the best. The greater pain caused by this drug could be largely obviated by an anaesthetic vehicle. When calomel could not be tolerated, he used mercurial cream, but in no greater concentration than 10 per cent. He would reserve mercury for cases in which bismuth was impracticable.

In the discussion following Colonel Harrison's paper, Dr JAMES MCINTYRE (co. Durham) said that in his area insoluble preparations of bismuth were found to give the best results. He worked in close association with tuberculosis officers, who were very definite in their opinion that arsenical preparations lit up a tuberculous focus. Many patients in this depressed area were suffering from under-nutrition, and among these, when arsenical treatment was employed, jaundice was found to be very marked. Dr E. T. BURKE (Salford) remarked that the rate of elimination of arsenobenzene remedies was so very rapid that in his clinic it was considered better to have the patient attend twice weekly than to give one single dose in a seven-day period. He considered it unsound to regard mercury as having any practical efficacy in the modern treatment of syphilis; it was an adjunct, like any ordinary tonic treatment.

Dr DAVID LEES (Edinburgh), who presided, substantiated what Colonel Harrison had said about sulpharsenobenzene preparations being responsible for aplastic anaemia. With regard to jaundice, he did not think that arsenobenzol was the sole cause, though it might be a contributory factor. But the amount of serious jaundice was infinitesimal; he had seen only three cases in about eleven years. The most important cause of intolerance to arsenobenzol treatment was the taking of alcohol during treatment. Mr Lees also suggested that the time had come when some method of creating pyrexia without the undoubted risks of malarial therapy should be devised.

INCIDENCE OF NEUROSYPHILIS IN THE TROPICS

An interesting discussion arose on a paper presented by Dr R. W. C. KELLY on syphilis in Singapore. He mentioned that in the social hygiene clinics in Singapore, hemiplegia, due to syphilitic cerebral thrombosis, was

often met with, but tabes dorsalis and general paralysis of the insane were infrequent, and the few cases of the latter which were seen generally occurred among those who did not perform hard manual labour. Dr. A. R. COOK (Uganda) said that in that Protectorate very few cases of locomotor ataxia or dementia paralytica were to be seen, and he could not recall seeing one case of general paralysis of the insane among the native population. Colonel HARPER NELSON (professor of medicine at Lahore University) said that during the twelve years he had been in Lahore he had seen only two cases of tabes dorsalis, and one of these was in a man partly of European descent; he had seen only one case of general paralysis, and that was in an Anglo-Indian. He thought it possible that the population had been immunized as the result of previous infections with malaria. Dr. A. O. ROSS (Liverpool) mentioned that he had seen many persons with neurosyphilis who were home from tropical countries, where they had had malaria. Dr. MYRTLE NORONHA (Bombay) suggested that the absence of neurosyphilis in India might be due to lack of treatment or to improper treatment of the syphilis, so that by the time the nervous manifestations appeared the people had acquired a sort of self-immunity. Dr. LOUISA PEARCE (New York) said that the difference between Occidental and Oriental syphilis might be due to a difference in the organism or in the reaction of the host. In the Belgian Congo she had seen secondary syphilis such as was not to be found in America or Europe, and it might be that after these manifestations the body acquired an immune state. Dr. A. G. COIA (British Guiana) said that in ten years there he had seen only two cases of general paralysis of the insane (one of them doubtful) and one case of tabes dorsalis. The cardio-vascular condition was very common in that country, and possibly cut off many who would otherwise go on to nerve manifestations.

Dr. DAVID LEES said that the absence of the grosser forms of neurosyphilis in the Tropics raised many problems. But the average age of death in India was 40 to 45, and most neurosyphilis in Western countries developed after that age. It seemed possible that in the Tropics people died before the age at which neurosyphilis would ordinarily appear.

ANTE-NATAL TREATMENT

Several papers were read on methods of dealing with ante-natal venereal disease. Dr. GLADYS SANDES gave an analysis of 1,000 consecutive deliveries at the London Lock Hospital since 1920. After giving details of the ante-natal treatment pursued, she made the deduction that the incidence of congenital syphilis was due primarily to the absence or inadequacy of treatment of the mother's syphilis during pregnancy. Dr. MARY MACNICOL of the Elsie Inglis Memorial Hospital, Edinburgh, followed with an account of similar work at that institution. She said that the ante-natal treatment of syphilis was comparatively satisfactory, but that of gonorrhoeal infection during pregnancy was less so. The danger to the child of ante-natal gonorrhoea had largely been removed, but such was not the case as regards the mother, who ran a three-fold risk: of immediate infection of the uterus during the puerperium; of the later development of chronic cervicitis, endometritis, and salpingitis; and of sterility following upon these conditions. Dr. DAVID NABARRO also spoke on the results of neglect of or inefficient natal treatment. The syphilitic mother, he said, could almost certainly beget a non-syphilitic child if she was adequately treated during pregnancy.

Observations from Africa and India were also brought forward. Dr. G. G. BUTLER described an investigation of material collected from the maternity hospital, Accra, Gold Coast, with the object of estimating the prevalence of syphilis among expectant mothers, and of forming an opinion as to what extent that disease was the cause of the high Wassermann positive rate in order better to assess the value of the reaction as an indication for initiating ante-natal treatment. Owing to the population being heavily infected with yaws the task was not easy, and a cross-immunity between yaws and syphilis was suggested. The investigation showed a remarkable infrequency of obvious syphilis in a local African community heavily infected with gonorrhoea and yaws. Dr. MARGARET BALFOUR discussed the ante-natal treatment of syphilis in India, for which, she said, there were two essentials: that women doctors should be employed, and that there should be a sufficient supply of necessary drugs, the latter a considerable problem because drugs were expensive and women's hospitals poor. The remedy would be for the municipalities or Governments to make grants to the hospitals. She was followed by an Indian woman doctor, Dr. MYRTLE NORONHA, whose idea was to have in every native town a maternity service unit, with an ambulance to reach the surrounding villages. A beginning in this direction, she said, had been made in Bombay. Several missionary doctors took part in the discussion.

STERILITY

The final discussion was on sterility. Dame LOUISE MCILROY said that by far the greater number of cases of primary sterility in women were due to gonorrhoea. Secondary sterility might be due to gonorrhoea also, but in her experience it was due mainly to puerperal sepsis. Incidentally she urged the investigation of the husband as well as of the wife if no obvious lesions were present in the latter. Mr. KENNETH WALKER spoke on the influence of venereal diseases on male sterility. No accurate estimate, he said, could be given of the part played by venereal disease in the production of sterility, but it was safe to assume that gonorrhoea was by far the commonest cause of impaired fertility in the male. The absence of spermatozoa was not due to any damage inflicted on the seminiferous tubes, but to a blockage in the canal along which they must travel in order to emerge. The commonest site of this blockage was the epididymal canal. Since epididymitis was the complication most likely to produce sterility, all measures which reduced its likelihood, such as rest, and the giving of belladonna or atropine in cases of posterior infection, were useful. The only syphilitic lesion which was likely to affect male fertility was gumma of the testis, and since this occurred comparatively late in the disease it was not very often the cause of a childless marriage. He associated himself with Dame Louise McIlroy's remarks as to the advisability of examining the husband before subjecting the wife to an operation.

Many other features of the congress must be passed over with a mere mention. These included a discussion on ways in which the universities may encourage the teaching of biological science in secondary schools. There were discussions also on social customs in relation to venereal disease, on means of propaganda, and on the role of British women in social service over-seas. On the last day of the congress joint sessions were held with the International Union against the Venereal Peril, and papers on follow-up work from treatment centres in Paris and Florence, as well as from centres in this country, were presented. Sir BASIL BLACKETT, the president, also delivered his address from the chair on "Social hygiene and the structure of twentieth century life."

The congress was attended by delegates from home and oversea Government departments, universities, local authorities, and social organizations. The delegates for

the British Medical Association were Dr. H. G. Dain and Mr. Bishop Harman.

The dinner of the congress was held at the Café Royal on July 17th, when representatives from twenty nations were among the guests. Sir Basil Blackett, who presided, said that their object was very much an international affair. Referring to the great part which British women had taken in the work, he said that without such assistance their object would not make much progress. The aim of the British Social Hygiene Council was essentially prevention. Professor Winifred Cullis advocated the teaching of biology as necessary to the progress of the work.

BEIT MEMORIAL FELLOWSHIPS

MEETING OF TRUSTEES

A meeting of the Trustees of the Beit Memorial Fellowships for Medical Research was held on July 14th, for the election of Fellows and other business.

In his annual report the honorary secretary, Professor T. R. Elliott, F.R.S., recalled that last year a review was given of the work of the Beit Memorial Trust in the first twenty years since its foundation.[1] The close of 1930 marked the period that had been chosen for the review with a sharper line, by the death on December 8th of the Founder of the Trust, Sir Otto Beit. The Founder's generous resolve to perpetuate the memory of his brother, Mr. Alfred Beit, by augmenting more than fourfold the gift which the latter had wished to make for the progress of medical studies in the University of London, did not conclude with the endowment by £210,000 of the Trust. As chairman of the Trustees, Sir Otto devoted close thought to every step that might advance the aims of the Foundation, and showed the keenest interest and pleasure in marking those successes in the advance of medicine by research which have been achieved by the most distinguished of the Beit Fellows.

RESIGNATIONS AND APPOINTMENTS

At the same time the Advisory Board lost by resignation two of its members, the last of those who had served continuously since the creation of the Board. Sir Charles Martin resigned when his appointment as Director of the Lister Institute expired, and he left London to take control of some developments of medical work in Australia. The Trustees are deeply grateful to him for his twenty-one years of loyal service, not only on the Advisory Board, where the breadth of his knowledge in many fields of research and his sane judgement were invaluable, but also as the immediate director of laboratories in which so many Beit Fellows had the privilege of working under his control. The debt of the Trustees to him and to the Governors of the Lister Institute, who provided all laboratory facilities freely without further help from the Trust, is evidenced by the fact that out of the 137 Fellows elected since 1909 no fewer than 31 were assigned to work at the Lister Institute. The second resignation was that of Sir James Kingston Fowler, whose services in a different direction have throughout been of such essential importance that his name will stay in the history of the Trust very close to that of the Founder himself. As Dean of the Faculty of Medicine in the University of London, he bore a leading part in the original discussions with Mr. Alfred Beit, and then with Sir Otto Beit, with regard to the contemplated benefaction; and later as honorary secretary, being a Trustee as well as a member of the Advisory Board, he planned the administrative details, advised on policy, and for twenty-one years fostered every year's growth of the Foundation in which he took so high and so justly personal a pride. Though released from the routine duties of honorary secretary, he will still give service and guidance as senior of the Trustees.

The Trustees welcome the appointment as their colleague of Sir John Rose Bradford, who in 1909 was chiefly responsible for the advice that led to the Trust being guided to the creation of Fellowships rather than to other purposes, and who served for twelve years on the Advisory Board. Sir Alfred Beit, also, has consented to serve as Trustee in the place of his father, Sir Otto Beit. Dr. J. C. G. Ledingham, F.R.S., now Director of the Lister Institute, and Dr. P. P. Laidlaw, F.R.S., have been appointed to the Advisory Board. The Trustees offer their congratulations to Sir Frederick Hopkins, a member for many years of the Advisory Board, on his election as President of the Royal Society.

WORK OF THE BEIT FELLOWS

The number of Fellows now working on the Foundation, apart from those reported for election below, is twenty-three. The list of places recognized for research has long ago been widened beyond the limitation suggested by the first idea that work would be done chiefly in the laboratories and schools attached to the University of London, and, indeed, each year more and more Fellows are being permitted for special purposes to work even for a year abroad. The Fellows choose their own problems, and no attempt is made by the Board to select a subject and appoint a team to investigate it.

"It is therefore of interest to watch the subjects proposed and see how rapidly the tide of research swings first into one bay and then to another, in the pressure to find through allied sciences the means towards fresh advances in medicine. Bacteriology, for example, has so altered its landward approaches that among the present Fellows and the 39 candidates at this July election only a very few are content to attack the problems of microbic disease by the older charted ways. More of the voyagers now are exploring the coasts of biochemistry, and through fundamental studies by precise test-tube experiments on the metabolic activities of bacteria or on the modes of ferment action are seeking to understand their behaviour in the human body. Indeed, for these and like aims, there are of the present Fellows seven now clustered in the biochemical laboratories of Cambridge University."

The aim of the Fellowships is to start a man on the career of research, and it is to the after-careers that the Trustees look for proof that the Advisory Board has guided them well in the selection of Fellows.

ELECTION TO FELLOWSHIPS

The following elections were made by the Trustees:

Senior Fellowships (value £700 per annum).—F. R. Winton, M.A., M.D. To continue his work in the Pharmacological Laboratory of University College, London, on the tonus of plain muscle, on the blood pressure in the glomerulus of the kidney, and on the effect of drugs on kidney secretion.

Fourth Year Fellowships (value £500 per annum).—B. H. C. Matthews, M.A. To continue his work in the Physiological Laboratory, University of Cambridge, on the analysis of sensory nerve impulses by electrical records obtained with the delicate oscillograph which he has invented.

Junior Fellowships (value £400 per annum).—(1) Benjamin Stanley Platt, M.B., Ch.B., M.Sc., Ph.D. Re-elected to the Junior Fellowship which he had resigned in 1926 in order to obtain medical qualification and so fit himself more fully for medical research. He will work at the School of Medicine, Leeds, on problems of the alimentary canal. (2) William Albert Hugh Rushton, M.A., Ph.D. Cambridge. Proposed research on the chronaxie of nerve and muscle, in the Physiological Laboratory, Cambridge. (3) Leonard Hubert Strickland, B.A. Proposed research: an investigation of the metabolism of the anaerobic bacteria associated with gas gangrene, in the Sir William Dunn Institute of Biochemistry, Cambridge. (4) Muriel Elaine Robinson, Ph.D. To continue investigations on haemoglobin, and on the preparation of proteins in a pure state, in the Sir William Dunn Institute of Biochemistry, Cambridge. (5) Frank Burnet Byrom, M.D., M.R.C.P. Proposed research: a study of factors influencing the total water exchange of the human body in health and in disease, at the London Hospital (in continuation of work begun at Chicago as Rockefeller Fellow). (6) Janet Maria Vaughan, B.A., D.M. An investigation of the relationship of disordered haematopoiesis to those bone changes that are found in human disease, or which can be experimentally produced in animals, at the Institute of Pathology, London Hospital.

All correspondence of Fellows and candidates should be addressed to the honorary secretary, Beit Memorial Fellowships, University College Hospital Medical School, University Street, W.C.1.

BRITISH EMPIRE CANCER CAMPAIGN

ANNUAL GENERAL MEETING

The MARQUESS OF READING presided over the annual general meeting of the British Empire Cancer Campaign in the House of Lords on July 20th, and read a letter from H.R.H. the Duke of York congratulating the Campaign on its successful progress. The Duke referred specially to the Cheshire and North Wales branch, which had made special use of propaganda as a means of obtaining patients in the earliest stages, and commended for the consideration of the Campaign the instituting of such organized propaganda work throughout the whole country.

Sir WILLIAM WILLCOX moved the adoption of the annual report, which is summarized below, and insisted that real permanent stepping-stones were now being laid towards the objective of discovering the cause of cancer and the best lines of treatment. He agreed that propaganda efforts should be increased, and thought that this could be achieved at a relatively small cost.

Sir RICHARD GARTON, honorary treasurer of the Campaign, stated that there had been an excess of expenditure over income during the past year of £1,810. The present balance in hand was £65,841, and of this sum approximately £30,000 was earmarked to meet commitments, and for the continuation of research work which was already being carried on. He appealed for further generous support from the public so that the work of the Campaign could be pursued still more energetically.

Lord Reading was re-elected chairman of the Grand Council of the Campaign, and Lord Dawson and Sir John Bland-Sutton were re-elected vice-chairmen.

THE EIGHTH ANNUAL REPORT

The usual detailed survey of the progress made during the past year in cancer research in Great Britain and the Dominions is prefaced by Lord Reading's report as chairman. Special attention is called to " the production of a substance from artificially prepared anti-cancerous serum, which has not only cured implanted cancer in mice, but is also efficient in a certain proportion of spontaneous cancers occurring in these animals." The serum which was tried at first proved to be moderately effective, but its use was attended with grave toxic symptoms. By a chemical process the anti-cancer substance was separated from the toxic elements, and was then found to be ten times more effective in destroying cancer cells than the original serum. It causes the disappearance of implanted tumours in mice, and renders these animals completely resistant to further grafting. In two out of five mice with spontaneous tumours the growths disappeared. Some unknown factor seemed to be present in the three other cases, and efforts are being made to define its nature. Reference is made to Professor Mellanby's work at Sheffield on the metabolic changes of the cancer, and the conclusion reached that phosphate plays no part in cancer glycolysis. As regards the relation of diet to cancer, it seemed clear that foods rich in vitamins stimulated cancer cells no less definitely than normal cells, and did not prevent tumours from developing when an effective carcinogenic stimulus was present.

The Nature of Cancer

In a statement from the research institute of the Cancer Hospital the progress made in investigating the experimental production of cancer is indicated ; it is hoped by these researches eventually to find a means of preventing its development into the stage of a recognizable tumour. The possibility of a chemical factor being concerned is being explored, and the benzanthracenes and dibenzanthracenes, which are definitely carcinogenic, are being used in experiments. The number and position of the benzene rings in compounds of these series is possibly of some significance as regards carcinogenicity, but further research is necessary before it can be asserted that any definite information has been obtained as to an essential molecular structure of the cancer-producing agent in tar. It is concluded, however, that crude tar should no longer be used in experimental work; a pure substance is required in such investigations as those into the influence of dieting, for tar contains very many superfluous substances, some of which are irritating, and so the tests are confused and the results are fallible. In obtaining such a pure substance chemical separation processes have been combined with the method of fluorescence spectrum analysis, to which reference was made in last year's report.

Oxidative Power of the Cancer Cell

Both at Sheffield and in the research laboratories of the Middlesex Hospital biochemical factors in carcinogenesis have been investigated, and it now appears that a regular feature of all tumours is a weakness in the oxidation of carbohydrates. No definite correlation has been traced between malignant disease and the presence of lactic acid in the stomach contents. While interference with the oxidative processes of carbohydrates is a characteristic of tumour growths, it was not found in the case of normal embryonic cells, but it was present in certain other pathological tissues.

The Radium " Bomb "

Caution is expressed as regards the value of the radium bomb. The 4-gram apparatus at the Westminster Hospital Annexe has proved to be dangerous, rapid diminution of the blood cells occurring after twenty-five to thirty hours' treatment. There is a small decrease in the red cells, but the total white cell count falls from 7,000 to 3,000 or even less, the lymphocytes being particularly affected. The polymorphonuclear tends to occur, moreover, with a greater proportion of immature forms. When the exposures have been small, however, and spread out over a longer period of time, a definite increase in the white cell count has been detected. The damage caused was not irreparable, periods of rest being followed by a return to the normal. Treatment for one week impaired the urea concentration power in ten patients, and it seemed likely in some cases that damage had been caused to the kidney in the form of glomerular hypertrophy and oedema, and necrosis of the loops of Henle with shedding of the tubular epithelium.

Pelvic Cancer

An increase in the amount of radium available for the Marie Curie Hospital enabled a larger number of patients to be treated. A rather unexpected finding was that cases of adenocarcinoma of the uterus responded as well as those of squamous-celled carcinoma of that organ. In cancer of the cervix, conclusive evidence was obtained that the use of supplementary external irradiation when the parametria were invaded, and especially when there was fixation, materially increased the number of five-year cures.

Heredity and Cancer

The hereditary factor in intestinal polyposis was made the subject of a special investigation during the year at St. Mark's Hospital. It has now been shown that this disease is transmitted by both males and females, that both sexes suffer from it, and that the inheritance can be traced through several generations. If members of these families survive the other complications of polyposis and ordinary risks of life, they develop cancer of the rectum or colon, usually in the early thirties or forties.

STERILIZATION OF DEFECTIVES

AN UNSUCCESSFUL BILL

In the House of Commons, on July 21st, Major A. G. Church, M.P. for Wandsworth, asked leave to bring in a Bill "to enable mental defectives to undergo sterilizing operations or sterilizing treatment upon their own application or that of their spouses or parents or guardians." As recorded in our Parliamentary Notes, the Bill was rejected by 167 votes to 89. Its text was as follows:

STERILIZATION OF DEFECTIVES.

1. (1) It shall be lawful for a registered medical practitioner to perform a sterilizing operation as defined by this Act upon a defective not under the age of 16 provided the following persons and bodies, namely, (*a*) the defective, if he is capable of expressing himself as willing or unwilling to undergo the operation; (*b*) the spouse (if any) of the defective; (*c*) if the defective is unmarried, his parent or guardian (if any); and (*d*) the Board of Control, respectively consent to the operation being performed and the operation has been sanctioned by an order of a judicial authority for the purposes of this Act made upon the application of the defective or his spouse (if any) or his parent or guardian (if any).

(2) Notice of an application for such an order as aforesaid shall be given by the person making the application to all other persons authorized to make the application except in cases where such notice is dispensed with under this Act.

STERILIZING OPERATIONS, ETC.

2. For the purposes of this Act

(i) The expression "sterilizing operation" shall mean vasectomy salpingectomy and any other surgical operation whereby the patient is rendered incapable of procreation or child-bearing without the capacity to exercise the sexual functions being otherwise impaired;

(ii) Any medical treatment which attains the same result as a sterilizing operation with the same limitation in its effect as regards the sexual functions shall be treated as a sterilizing operation for all the purposes of this Act.

ORDER OF JUDICIAL AUTHORITY

3. (1) In any case where an application is made to a judicial authority under this Act for an order sanctioning a sterilizing operation, the judicial authority, provided it is satisfied by such medical certificates or other evidence as it may deem sufficient and after such visitation or inspection as it may direct and after hearing and considering any representations made by any person to whom notice of the application is required to be given by this Act (i) that the person to whom the application relates is a defective; (ii) that there is no probability of the health of such person being adversely affected by the operation; and (iii) that the several persons and bodies whose consent to the operation being performed is required by this Act have respectively given such consent, shall have power to make an order sanctioning the performance of a sterilizing operation as defined by this Act.

(2) Such an order of the judicial authority shall be conclusive for all purposes as to (i) the person to whom the order relates being a defective; and (ii) the consents to the operation being performed required by this Act having been given.

PROTECTION OF MEDICAL PRACTITIONERS

4. (1) A registered medical practitioner shall not in any case where he has with due care performed a sterilizing operation under the authority of this Act be liable to any criminal or civil proceedings in respect of such operation.

(2) Nothing in this Act shall render unlawful any surgical operation or medical treatment which before the passing of this Act could lawfully be performed or applied.

JUDICIAL AUTHORITIES: REGULATIONS AS TO PROCEDURE

5. (1) Every judicial authority for the purposes of the Mental Deficiency Acts shall be a judicial authority for the purposes of this Act with the like jurisdiction and powers as under those Acts.

(2) The Secretary of State may make regulations with respect to the procedure on application for orders under this Act.

NOTICES, ETC., DISPENSED WITH IN CERTAIN CASES

6. (1) In any case where the parent, guardian, or spouse of a defective (i) cannot be found; or (ii) is outside Great Britain; or (iii) is a person of unsound mind lawfully detained under the Lunacy Acts, 1890–1892, or a defective; or (iv) is undergoing imprisonment (except under civil process) or penal servitude, the judicial authority shall have power to dispense with any notice to or consent by such parent, guardian, or spouse which would otherwise be required under this Act.

(2) For the purposes of this Act (i) the expression "guardian" shall include any person who undertakes or performs towards a defective the duty of a parent or guardian or has charge of him; (ii) the consent of or notice to any one or more of a number of persons who with reference to a particular defective come within the designation of parent or guardian shall be sufficient consent of or notice to a parent or guardian.

INTERPRETATION AND ADAPTATION

7. In this Act (i) the expression "Mental Deficiency Acts" means the Mental Deficiency Acts, 1913 to 1927, as amended by any subsequent enactment; (ii) the expression "defective" has the same meaning as in the Mental Deficiency Acts.

SHORT TITLE AND EXTENT

8. (1) This Act may be cited as the Sterilization Act, 193 .

(2) This Act shall not apply to Scotland or Northern Ireland.

India

The Calcutta School of Tropical Medicine

A series of interesting accounts of research along many lines is to be found in the joint annual report for 1930 of the Calcutta School of Tropical Medicine, Institute of Hygiene, and the Carmichael Hospital for Tropical Diseases. This composite organization affords a fine example of the value of team work, and of the co-ordination of investigations in such different spheres as pathology, pharmacology, chemistry, and tropical surgery. The director of the Calcutta School, Lieut.-Colonel H. W. Acton, I.M.S., comments in a preliminary note on the difficulties which have been overcome during the year. Thus, the housing of the Pasteur Institute at the School takes up valuable space; even so, during the hours of inoculation, 400 patients have to crowd into a small room only about 20 by 30 feet. Sepsis and tetanus would seem inevitable complications of inoculating in such circumstances, but, so far, no accident has occurred, probably because the street dust contains only avirulent spores of these organisms, owing to the sterilizing action of the sun. Financial stringency has prevented the building of a separate wing for this Institute, but Colonel

Acton writes most warmly of the way in which the School is being supported by local societies and organizations, no fewer than five research chairs being thus subsidized, and several minor researches being rendered possible. The Indian Research Fund Association, moreover, maintains two professorial chairs at the School—namely, those of bacteriology and protozoology. The Tea and Jute Associations, in spite of their own financial difficulties, have guaranteed their generous annual grant for another five years. It is noted that in elephantiasis the frequent acute attacks of sepsis and cellulitis have now been traced to the occurrence of septic foci either on the skin or in the teeth, tonsils, prostate, or intestines. From time to time organisms pass into the blood stream from these sites, and invariably choose those areas where the local defence has been lowered by the irritation caused by the infecting *Filaria bancrofti*. Vaccines are now given to diminish the inflammation from such local foci. In the direct treatment of the lesions mercury, arsenic, bismuth, and antimony have been employed without avail, but tryparsenamide has proved effective in chyluria. One important therapeutic point elucidated has been the necessity of infiltrating the tissues below the lesions. During the last three years great advances have been made in perfecting the efficacy of antirabic treatment, and it has been concluded, on the basis of 3,000 cases observed, that the mortality rate for all badly bitten persons, if untreated, ranges from 6 to 10 per cent. In each of the three years approximately 1,000 persons have been treated who would be grouped in this category, and the death rate has remained about the level of 2 per cent. Such a saving of life of from 4 to 8 per cent. in this disease has, it is claimed, not been achieved by any other institute in the world with such consistent success over a three-year period. An important step in the securing of better clinical results has been the use of sheep instead of rabbits for the preparation of the antirabic vaccine. Inoculations must be begun as soon as possible after the bite ; this involves further decentralization of the vaccine treatment in order that indigent patients living far away may be dealt with. The whole report of the Calcutta School this year, with its various subsidiary statements on the progress made in tropical medicine, bacteriology, protoozology, serology, pharmacology, and the other lines of research, is one of the most interesting and important that have yet appeared.

Treatment of Plague

The report of the Haffkine Institute for 1929 has recently been received, the delay in its issue being due to the fact that late in that year it was decided to change the method of publishing the statistics and to hold up the clinical reports until the lapse of six months after the completion of treatment, instead of waiting only three months as heretofore. The demand for Haffkine's plague vaccine during the year under review is stated to have decreased a little, probably in consequence of the lowered incidence of plague ; there is good reason to believe that the value of this protective measure is being increasingly realized, for as soon as an epidemic occurs urgent requests are made for its supply. Certain problems in connexion with the preparation and keeping powers of the vaccine have been considered by a committee of the Institute, and it has now been shown that batches can be used in the usual doses until eighteen months from the date of their manufacture, and even up to a total period of two years provided that during that period they have been kept in cold storage. The period of preparation can be reduced from twelve to six weeks without marked loss of efficiency. The present broth vaccine which is employed seems to be superior as regards its immunizing value to the agar vaccine which had been suggested as a substitute. Evidence has been received from other countries that a satisfactory degree of immunity is obtainable there from approximately half the dose used in India ; at present, however, it is thought unwise to authorize any reduction of the dosage in India until it is certain that the improvements recently introduced in preparing the vaccine have not diminished its immunizing power. The report contains an interesting account of the processes of manufacture and of the special steps taken to prevent contamination. Standardization has proved to be very difficult, owing to broth vaccines being concerned ; the method previously employed was empirical, depending mainly on the length of incubation of the organisms. Considerable advance has recently been made in devising and perfecting a biological mode of standardization, which it is believed will be much more accurate. Researches on the flea factor in plague epidemiology have been continued at the Institute, and three species are now believed to be carriers. An attempt has been made to produce a potent anti-plague serum, and sheep and calves are being utilized in the preparation of a large stock of serum, which can be tested clinically on a sufficiently extensive scale. Chemotherapeutic research is being actively continued, the drugs at present in favour being the halogen compounds of mercury and phenol. The antirabic section of the report is less satisfactory ; the returns from many distributing centres are said to be very poor, and statistical evidence as regards the clinical results is therefore inadequate. The Paris strain of fixed virus is now being exclusively used for the treatment of patients at the Institute.

Vaccination Progress

The Government report on vaccination in Burma for the year 1929-30 states that the numbers of persons vaccinated and re-vaccinated each year in the province have steadily increased during the last decade. This is held to be the natural result of a gradual realization on the part of the people of the value of vaccination and their consequent willingness to accept it. Where there has been a decline this has for the most part been attributable to comparative freedom from small-pox. The reason for the increase in the Bassein district is said to be that " Burmese sages predicted an outbreak of small-pox in the year 1930-31, and the people resorted to vaccination as a means of protection against it." This prediction coincided with the forecasts by several health authorities of a general small-pox epidemic about this time, and strengthened the hands of the authorities. In the North-West Frontier Province similar steady progress in vaccination is reported, although there has been a decrease in the number of vaccinators employed. The ratio of successful vaccination per thousand of population during 1929-30 was also much higher, and re-vaccination increased concurrently, the prevalence of small-pox in some parts of the province rendering the population more willing to be so treated. The glycerinated chloroform lymph supplied by the Punjab Vaccine Institute was used during the year and gave satisfactory results. In Madras the attempted decentralization in the administration of vaccination in rural areas has been attended with considerable difficulties, there being a good deal of administrative opposition, which calls for legislative action. The notification of small-pox is also unsatisfactory, and serious discrepancies have been detected in the returns for some districts. About 85 per cent. of the deaths from small-pox during 1929-30 occurred in children under the age of 10. Encephalitis as a complication of vaccination has not been reported in the Presidency so far. Elaborate arrangements have, nevertheless, been made in the King Institute for a thorough examination of every batch of lymph, only such lymph as satisfies every test being now issued.

Scotland

New Edinburgh Professor

The curators of the University of Edinburgh have appointed Dr. A. Murray Drennan, who is at present professor of pathology in Queen's University, Belfast, to the chair of pathology in the University of Edinburgh, in succession to the late Professor Lorrain Smith. Professor Drennan was born in 1884, and after studying medicine at the University of Edinburgh, graduated M.B. with first-class honours in 1906. His thesis for the M.D. degree, which he took in 1924, was awarded a gold medal. In 1908 he became a Member of the Royal College of Physicians of Edinburgh, and proceeded to the Fellowship in 1914. After acting as an assistant to the late Professor Lorrain Smith in the department of pathology at Edinburgh, he was appointed professor of pathology at Otago University, Dunedin. During the war he served with the 22nd and 27th General Hospitals of the Mediterranean Expeditionary Force. He has contributed various articles to pathological literature.

River Pollution in Scotland

The Scottish Advisory Committee on Rivers Pollution Prevention, which is conducting a series of investigations, has recently reported to the Department of Health for Scotland in regard to the River Esk, Midlothian. This river, which passes through several towns concerned especially with the paper-making industry, discharges into the sea a few miles east of Edinburgh. Effluents from the paper mills cause the river to be greatly discoloured, to be covered from time to time with froth, and at times to smell very badly, so as to constitute a nuisance. The Royal Commission suggested that an average standard of purity for river water was that it should take up 0.2 part per 100,000 of dissolved oxygen in five days, while a nuisance may arise when the river water takes up 0.4 part per 100,000. It was found that the Esk, after passing the first paper mill in its course, took up 0.32 part of dissolved oxygen, and that each successive mill aggravated the condition, so that in the lower part of the river the water had to be purified even for manufacturing purposes. In the last stretch the river was further polluted by the addition of coal dust from neighbouring mines. Further measures were also found to be necessary in order to deal with the sewage from the towns situated on the river. It is pointed out in the report that the administrative position has been greatly simplified by the passing of the Local Government (Scotland) Act, 1929, which makes the county council of Midlothian the only local authority for the administration of the Rivers Pollution Prevention Acts as regards this river. The report also suggests that the county council should appoint a river inspector or inspectors to inspect purification works, to take samples of trade waste waters for analysis, and to report to the county council.

Chalmers Hospital, Edinburgh

The Dean and Faculty of Advocates, Edinburgh, who are the trustees of Chalmers Hospital, held a meeting on July 10th to consider proposals for improvements at this institution. The estimated cost of the scheme was stated to be £10,000, which was covered by a donation from the trustees of the late Mr. Edward Clark, printer, Edinburgh. The scheme includes the erection of a new wing for an *x*-ray department and an operating theatre. The hospital was founded in 1864 through a bequest of approximately £30,000 from George Chalmers, a plumber in Edinburgh, and consists of four wards, of which two are charitable and two are intended for the use of paying patients. It was one of the earliest in the country to have paying wards, and this arrangement has been very popular from the time of its institution. The hospital, which is maintained entirely by its endowment funds, and by the payments of patients, makes no claim on the public for subscriptions.

Arbroath Infirmary

A new wing, including a children's ward and accommodation for nursing staff, was opened recently at Arbroath Infirmary. The extension has cost £17,680, towards which a sum of £15,756 has already been subscribed. In declaring the buildings open, Sir John Cargill sketched the history of the institution since its foundation in 1843, and remarked that in the first year of its existence sixty-six patients had been treated at a cost of £25 per patient, whereas in the past year 879 patients had been treated at a cost per patient of £105.

Correspondence

PRIORITY IN NEUROLOGICAL SURGERY

SIR,—May I, as one of Victor Horsley's former pupils and colleagues, do a tardy justice to his acknowledged greatness both as a neurologist and as a surgeon by pointing out in your columns the inaccuracy of the oft-repeated claim in American publications that Spiller of Philadelphia, in 1898, was *the first* to suggest section of the sensory root of the fifth nerve for the relief of trigeminal neuralgia? I am the more prompted to do so by the appearance in the *Journal of the American Medical Association*, March 21st, 1931, of the last article of many by Dr. Charles Frazier, in which he continues to advance this claim, and further states: "The first purposeful section of the sensory root for the relief of trigeminal neuralgia was performed in this clinic."

Neither of these claims can be substantiated. It was Victor Horsley who first suggested the procedure, and who first carried it out, exactly eight years prior to the appearance of Spiller's suggestion contained in his paper, written in collaboration with W. W. Keen, in the *American Journal of Medical Sciences*, November, 1898. In the *British Medical Journal*, December 12th, 1891 (p. 1249), in the last of three consecutive articles, written in collaboration with Drs. James Taylor and W. S. Colman, Horsley says: "In considering the possibility of relieving cases of inveterate neuralgia where recurrence of the pain had taken place [that is, after peripheral operations], I thought one might be able to remove the Gasserian ganglion *or divide the fifth nerve behind it* [italics mine], and I made, some years ago, dissections to see how far the Gasserian ganglion could be separated from the cavernous sinus. . . . Finding this to be the case [that complete removal of the Gasserian ganglion is not possible], I then considered the possibility of *dividing the fifth nerve behind the ganglion* [italics mine]. On trying this on the dead body, I found that it was perfectly feasible."

Horsley then proceeds to describe very fully the various steps of the operation, done on December 11th, 1890, which he deliberately undertook and performed for attacking the sensory root behind the ganglion. Further, in the *Clinical Journal*, November 3rd, 1897, he refers again to this case, and says: "In 1890, after consideration of the whole question in a very severe case, I determined to divide the nerve roots behind the ganglion. . . . To attain this object (post-ganglionic section) I endeavoured to raise the temporo-sphenoidal lobe, and succeeded without much trouble in detaching the sensory root from the pons."

I am sure that it will need only this letter to secure from our American confreres their ready and generous

acknowledgement of Horsley's priority in both suggesting and carrying out the operation of section of the sensory root for the relief of trigeminal neuralgia.—I am, etc.,

DONALD ARMOUR.

MINERS' NYSTAGMUS

SIR,—Dr. Roche has given an example of scientific method in his study of lighting effects at the coal face and their bearing upon the production of miners' nystagmus. May I ask his help in applying the same method to that and other disorders that he mentions?

Miners' nystagmus, shell-shock, and telegraphists' cramp are, he says, neuroses. In this connexion what is a neurosis, and can he enlighten us about its physiology? He tells us about reserve nervous energy, as to which I am curious about the possibility of measurement by means akin to those used in the measurement of reflected light, so that we may know when exhaustion, with its sequel of nervous breakdown, is approaching. How are we to detect that reserve nervous energy in the periphery of the retina, which is somehow used up in this disorder? And in nervous breakdown, what is it precisely that breaks? Perhaps Dr. Roche will make these points clear whilst assuming in his readers that minimum of physiological knowledge demanded before qualification.—I am, etc.,

MILLAIS CULPIN,
Professor of Medical Industrial Psychology, London School of Hygiene and Tropical Medicine.

London, W.1, July 16th.

OPERATION FOR CATARACT

SIR,—Mr. Traquair's letter in the *Journal* of June 6th raises points of practical interest—treatment in the case of patients where one eye has cataract and the other none. Post-graduates and students in the Eye Infirmary, Medical College, Calcutta, are taught that as soon as a cataract is mature it should be removed, and that the advantages gained from removing the cataract in one eye, when the other eye has none, far outweigh the disadvantages. Doubtless the resulting anisometropia makes the use of glasses for both eyes impossible, but it is not always necessary to use an opaque glass before one or the other eye. Improvement in the field of vision is valuable to everyone, especially anyone working among machinery or traffic. Secondly, after a successful cataract extraction the patient has an eye which can be corrected for vision as soon as the other eye becomes unserviceable. The mental effect of this is very great, as the patient is now convinced that he can never be blind. He is also relieved of the anxiety of a serious operation on which his vision depends. A mature cataract left in an eye becomes in the course of time hypermature, with its attendant dangers. I have frequently seen low forms of iridocyclitis produced by hypermature cataracts, and subluxation of the lens is also not uncommon. Secondary glaucoma due to cataract is very common in Bengal, amongst both Europeans and Indians, and a large number of operations are performed annually for this serious complication.

Personally, I always advise an elderly patient to have a cataract removed as soon as it is mature, because, as a rule, sooner or later cataract will appear in the other eye. In juvenile and pre-senile monocular cataract one hesitates to advise removal until the cause is known, because many of these cases are complicated. One does see cases, however, where the cause cannot be determined and all examinations prove negative and the cataract can be removed, good vision resulting in the majority of cases—I am, etc.,

E. O'G. KIRWAN,
Lieut.-Colonel I.M.S.

Calcutta, July 3rd.

DIVERTICULA OF THE COLON

SIR,—I must apologize for not having noticed earlier the letters of Dr. Gilbert Scott and Dr. John Muir which appeared in the *Journal* of April 11th.

Dr. Gilbert Scott, in referring to the paper by Mr. Lockhart-Mummery and myself on diverticula of the colon and their sequelae, draws attention to the necessity of examining the colon twenty-four hours after the opaque enema has been administered. I fully agree, and would go even further by saying that the examination must be continued until the lumen of the bowel is completely empty of barium. I thought I had made this point clear when I said that " these pockets retain the barium long after the lumen of the colon is empty, which distinguishes the radiographic appearances of the condition from any other."

With regard to Dr. Gilbert Scott's contention that the ring-like shadows in the diverticula are not due to retained faecal concretions in the pockets, but to residual barium in the diverticula at twenty-four hours, I should like to point out that in the paper I am referring to pockets which are visualized as ring-like shadows at the time of the injection of the enema, and in post-mortem examinations of patients who have been *x*-rayed—and who have died of other conditions, such as superadded carcinoma of the colon—and also from the follow-up of cases after treatment in which these ring-like shadows have disappeared when the pockets have been successfully evacuated, I have been able to convince myself that these ring-like shadows seen on injection of the barium are due to retained concretions.

Dr. Muir draws attention to the necessity for a careful screen examination, with which I fully agree. But again I thought I had made this quite clear at the commencement of that section of the paper dealing with the observations of the barium enema, when I said, " the patient is carefully screened during the injection of the barium enema," and when " the patient is rotated to the left so as to bring the whole length of the sigmoid flexure into view," etc. But though the screen examination is as important as the radiographic, it is not more important, as no screen examination, however careful, can take the place of good radiograms taken in different positions so as to show the lesions which have been observed under the screen. A report on the screen examination is " hearsay " evidence, and its value is relative to the competence of the witness ; whereas good radiograms which clearly show the condition are evidence capable of ocular demonstration to the surgeon or physician in charge of the case. In addition, however careful a screen examination may be, it is only for a brief period of time, whereas a film can be carefully studied at leisure, and serves as a permanent record. Lastly, minimal changes in the colon of an obese patient can be seen very much more clearly on a good radiogram than directly with the eye, however keen. The screen examination is extremely important for visualization of the general condition, and for adhesions, points of tenderness, the positions of palpable swellings in relation to the colon, etc. ; but the screen and the radiographic examination are two component parts of the whole ; neither can be used as a substitute for the other, and both require equally thorough technique.—I am, etc.,

H. GRAHAM HODGSON.

London, W, July 13th.

SIGNIFICANCE OF A RAISED BLOOD PRESSURE

SIR,—A very charmingly phrased address like that of Professor John Hay in the *Journal* of July 11th has a tendency, by its indefiniteness, to lead one astray ; and as he says " no one can now afford to be indifferent to the problems associated with variations in blood pressure," he will, I feel sure, pardon me for criticizing some points in the address.

First of all, he does not give us his definition of either systolic or diastolic pressure, and unless one has a clear idea of the subject treated it is difficult to appreciate all the points as satisfactorily as one would like to. Personally, I want to know whether Professor Hay considers that the diastolic pressure is the same in all the arteries, and, if not, why not?

Secondly, we are told that "to take a blood pressure reading is simple enough," and yet he suggests that in some instances the technique is not satisfactory, and that the records are unreliable. If the technique is unsatisfactory, how can the working of it out be simple? Is there any wonder that the records are unreliable?

Thirdly, Professor Hay states that "high pressure is not infrequently encountered in the young." May I add that in every case of acute rheumatism the basic blood pressure, as taken by my method, is raised as well as the systolic pressure. The basic blood pressure is raised in every case of chorea, as stated by me in the *British Medical Journal* of February 21st, 1931, where I pointed out that the symptoms subside as the pressure becomes lower. Every toxin or poison tends to raise the basic blood pressure.

Fourthly, we are told that "high blood pressure may be latent," but is not this a rather misleading phrase? Because the pressure has not been estimated one cannot say that it is not raised, and the fact that it is raised in chorea may account for some of the psychological abnormalities. In my opinion the choreic abnormalities are due to a metabolic disturbance in what I have called "an acid child," and I feel it is more correct to say that a disturbance of blood pressure is responsible for melancholia than that "mental pain and physical passivity" invariably induce a raised blood pressure.

Professor Hay points out that the tendency is to take too high a reading, but if the technique is unsatisfactory and the records are unreliable, one is tempted to ask whether the figures he cites are to be taken into serious consideration. I may be allowed to draw attention to the fact that the narrower the armlet the higher is the recorded systolic pressure. My method necessitates the use of two narrow armlets, so that they may be applied to the same arm, and for this purpose Messrs. Anderson Ltd. have made them for me, measuring 2½ in. by 12 in.—I am, etc.,

Swansea, July 12th. G. ARBOUR STEPHENS.

SIR,—Professor Hay's lecture on arterial hypertension, printed in your issue of July 11th, is admirable indeed. Yet it is the best demonstration of the fact that the significance of the ophthalmoscope in medicine is badly underestimated. Many gaps in diagnosis and many doubts in prognosis, as recognized by Professor Hay, would not exist if the help of a trained ophthalmologist were sought.

The retinal vessels are the first to suffer in essential hyperpiesis. So long as they are not affected, the arterial hypertension may be regarded as temporary. But the usual optimistic reading of the blood pressure by the medical man will quickly vanish when he realizes that the retinal vessels (it means the cerebral vessels too) are deeply degenerated. Moreover, it often happens that the blood pressure remains constant, and sometimes it even falls, but the degeneration of the retinal vessels progresses and makes the prognosis gloomy.

The so-called "sudden vascular accident or death" of a hyperpietic is usually the fruit of a deficient medical examination. Such a patient ought to be warned before of the seriousness of his position. I have still to see a patient with, say, diastolic pressure of 120 (the systolic is not so important), whose retinal vessels are healthy. "Dans la nuit, où nous sommes tous, le savant se cogne aux murs, tandis que l'ignorant reste tranquillement au milieu de la chambre" (Anatole France). The "savant" is the medical man; and one of his surest foundations for the diagnosis, prognosis, and even treatment of arterial hypertension is the ophthalmoscope. The "ignorant" is, of course, the hyperpietic himself.—I am, etc.,

London, E.1, July 12th. N. PINES.

HISTORY OF PROSTATECTOMY

SIR,—On reading the article headed "Sir Henry Thompson" in the *Journal* of July 11th (p. 70), I notice a quotation from Mr. Buckston Browne: "The late Mr. A. F. McGill of the Leeds General Infirmary in 1889 was the first surgeon who ever systematically removed all that can be removed of an enlarged prostate."

While attending a short post-graduate course at St. Thomas's and Soho Hospitals I had the good fortune to be present at the meeting when Mr. McGill read his paper on prostatectomy. That was in the last quarter of 1887—not 1889. I do not recollect the exact date, but it must have been in one of the last three months of 1887, when I was in London. It happened that Mr. McGill came to the bench where I (a stranger to him) was seated, and some friend called across the room, "How do you feel about it?" and the reply was, "Rather shaky." Sir Henry Thompson presided, and was evidently impressed by the account of the operation, for he remarked, "I never heard of anything like this before" As I recall Sir Henry, he was a dapper little man with a rather florid complexion and a full white moustache, and he was in faultless evening dress.—I am, etc.,

Balfron, Stirlingshire, July 11th. D. SINCLAIR.

VITAMIN B_2 AND PELLAGRA

SIR,—It was with considerable interest that I read the article on vitamin B_2 and pellagra, by Dr. B. C. Guha, which appeared in the *Journal* of July 11th (p. 53). It seems to me that experimental pellagra in rats bears but little resemblance to the human disease. Because a rat fed on a diet, deficient in certain essential principles, becomes mal-nourished, fails to grow, loses its fur, and develops buccal lesions and a dermatitis, does not seem to me a sufficiently adequate reason to label the condition "experimental pellagra." In the diagnosis of the human analogue the symmetry of the erythema is a point of great importance, so much so that, despite the presence of the characteristic buccal lesions, one would hesitate to label the condition pellagra, unless accompanied by the symmetrical dermatitis which is undoubtedly the most characteristic feature of the disease. I have seen cases of pellagra in children, but failure of growth and loss of hair have not been much in evidence.—I am, etc.,

HORACE M. SHELLEY,
London, W., July 14th. M.R.C.S., D.T.M. and H.

PLUMBISM

SIR,—In the issue of the *Journal* of July 18th due importance is paid, in the articles by Dr. Edwin Bramwell and Dr. Norman Porritt, to the part played in the causation of plumbism by drinking water of the soft, acid, peaty, or moorland class. It is, however, not generally known that the property of plumbo-solvency is not confined to waters of this class. We have met several instances of very hard well waters which were markedly plumbo-solvent, and gave rise to severe lead poisoning among the consumers. A word of warning is necessary, for it is unsafe to assume that because a water is hard that contact with lead may take place with impunity.—We are, etc.,

Medico-Legal

INJUNCTION AGAINST PROPRIETOR OF DRUG STORE

BRITISH MEDICAL ASSOCIATION v. MARSH

In the Chancery Division of the High Court of Justice, before Mr. Justice Maugham, on July 14th and 15th, an injunction was asked by the British Medical Association to restrain Mr. James Josiah Marsh, trading as Marsh's Manufacturing Chemists and the "B.M.A. Drug Stores," at 106, Borough High Street, S.E., and 186, Walworth Road, S.E., from representing that the drugs or medical or toilet preparations which he offered for sale were offered for sale by or on behalf of the Association, or from representing that he was carrying on business as a department of or in connexion with the Association, or from carrying on business or advertising or issuing to the public circulars under the name of the Association or the description "B.M.A." or "B.M.A. Drug Stores," or under any other name or names or description containing the letters B.M.A. in juxtaposition.

Mr. R. P. Croom-Johnson, K.C., and Mr. H. C. Dickens, instructed by Messrs. Hempsons, appeared for the plaintiffs, and Mr. Archibald Pocock and Mr. J. A. Lincoln Reed, instructed by Mr. G. L. Borradaile, for the defendant.

CASE FOR THE PLAINTIFFS

The plaintiffs alleged that at each of the stores the defendant displayed signs, cards, and posters bearing the letters "B.M.A.," and exhibited for sale and sold drugs and medical remedies bearing the letters "B.M.A." on the bottles or boxes containing them, and that he issued bills, labels, advertisements, and circulars in connexion with the sale of them, bearing the inscription "B.M.A. Drug Stores" and "B.M.A.," and containing references to the plaintiffs by their full name.

The defendant admitted these allegations, but contended that the letters B.M.A. did not exclusively or necessarily denote the plaintiffs, and that he was entitled to use the letters.

JUDGEMENT

In giving judgement Mr. Justice Maugham said that he could well understand there was a most important question of law, but on the questions of fact that arose he had been unable to see that there was anything to argue at all. His Lordship then continued:

The plaintiffs are the British Medical Association, a company registered under the Companies Acts, not for gain, and therefore entitled to carry on business without the addition of the word "Limited." It is an exceedingly well-known Association, first registered under the Companies Act in 1874, but the Association dates back to 1832—that is to say, just short of a hundred years ago—being then an unincorporated body. It has no less than 35,000 duly qualified members, and is a body that represents the opinion of the medical profession as a whole, and has been so recognized in various Government inquiries. It publishes a journal; it is constantly referred to in the public press, as appears from a large number of press cuttings which have been proved in this case; and it has also published, amongst other things, two publications, described respectively as *Secret Remedies*, and *More Secret Remedies*, the first in 1909, and the second in 1912. It is the nature of those two publications that has led to the activities of the defendant, and therefore, indirectly, to this action. The plaintiffs were concerned with the enormous growth of the proprietary articles which the public were induced to buy for the remedy of all sorts of ailments, and they were of the opinion that the remedies contained in proprietary and patent articles sold and broadcast over the country were in many respects remedies which were useless, if not harmful, and that they were sold at prices which bore no relation to the real prices of the ingredients. Accordingly, they caused analyses to be made of a number of the proprietary articles in question, and they published these analyses in the two books in question. There is no doubt that they thereby showed the public that a large number of the remedies in question were articles containing quite common substances, that in many cases the remedies were useless and that in some cases the remedies were positively harmful, and that in practically every case the proprietors of these remedies were charging for them sums which were greatly in excess of the value of the substances of which the remedies were composed. The two books had a large sale, and were, as I understand, reprinted on one or two occasions. The defendant came to the conclusion in 1923 that there was a profitable business to be carried on by taking from the analyses made for the plaintiffs the information necessary for making the proprietary remedies, by advertising to the public the fact that the articles made by him from those analyses were in effect precisely the same as the proprietary remedies, and selling them at a very much lower price. That was a perfectly legitimate idea. What was not legitimate was to pretend, if he has pretended, that the business so carried on was carried on as a branch of or with the assistance of or with the approval in some shape or form of the British Medical Association. It is apparent of course, that the British Medical Association were opposed to any of these remedies being used by the public without consideration and without medical advice, and are also opposed to the use of any secret remedies at all. The defendant, however, began in 1923 by forming a company . . . under the name of Public Prescriptions Limited, incorporated on June 2nd, 1923, with a capital of £500, divided into 500 shares of £1 each. . . . The Memorandum and the Articles were signed by a Mr. Hart, by the defendant, and by an Albert Edward Parkes, who was described as an analytical chemist. How far the company described itself or intended to make people believe that it was associated in some way with the British Medical Association I do not know, and it is not necessary to determine. The defendant says that at some date he adopted the letters "B.M.A." in a diamond as a trade mark, and some corroborative evidence has been given as regards that. An explanation has been suggested as to the reasons for the adoption of those three letters by the company; I shall return to that matter, because I want to conclude the story so far as it relates to the company.

His lordship then referred to the winding up of the company by reason of its liabilities, following an extraordinary resolution which it passed in July, 1926. It appeared from the evidence that the defendant had taken over, without any agreement or payment to himself as liquidator, the remaining stock of the company, its alleged trade mark "B.M.A." in the diamond, its bottles, its labels, and its other papers, and that he had used the labels up to the present time for the purposes of the business. During its existence the company had no shop, and carried on, or professed to carry on, a wholesale trade. About January, 1930, however, the defendant set up at any rate two shops, one at 186, Walworth Road, and the other at 106, Borough High Street. His lordship then went on:

Now when the shops were set up by the defendant, he chose to adopt a method of trading as to which I think there can be no doubt at all so far as concerns the conclusions that he wished the public passing his shops or entering them to draw. Taking the shop at 186, Walworth Road, it is apparent from an examination of the agreed photograph of the front of that shop that the passer-by sees at the top of it, taking up quite a large proportion of the window, the letters "B.M.A." in a diamond, with under it the words "Drug Stores"; in other words, the shop is represented as being the B.M.A. Drug Stores. Beneath that, in the window, I see exposed a guarantee beginning with the words "We guarantee." Across that, in wide letters, are the words "Why pay more? See what you save"; and beneath that I see, written out in conspicuous letters, the words "The British Medical Association." When I look at the whole of the card which is so exposed in the window, the full guarantee is this: "We guarantee," which is in large red letters two inches high, and then follow the words "that all reproductions of patent medicines are prepared strictly to the analyses of"; and then below is written again, in large red script, "The British Medical Association." It is wholly beyond doubt, to my mind, that the words "The

British Medical Association" there under the words "We guarantee" are so written for the purpose of leading the members of the public to think that "B.M.A." above is the same as the British Medical Association. If that alone were true, it seems to me that there can be no doubt as to the right inference to be drawn; but beneath the guarantee are three or four rows of bottles: the bottles are in pairs, and behind the pairs of bottles there are a number of cards which have been exhibited in this case. I will take the one with regard to "Phosferine" as an example. On the left-hand side of the card are the words "Phosferine, B.M.A. Analysis," and then there follow the five materials of which "Phosferine," according to the analysis of the British Medical Association, is composed. Below are the words "One quarter ounce bottle, 1s. 3d." On the right-hand side of the card I find this: "Nerve Food," below that "B.M.A." in a diamond, and then follow the words "is guaranteed to be made exactly from the same analysis. One and a half ounce bottle, 1s. 0d." It seems to me perfect waste of time to labour the point that "B.M.A. Analysis" there means "British Medical Association," and that "B.M.A." in the diamond refers to exactly the same thing as "B.M.A." in the words "B.M.A. Analysis," and that they both refer to the same "B.M.A." that is above the fascia of the window, which, as I think, quite clearly is the British Medical Association, who have given the large guarantee mentioned in the card. It looks as if the British Medical Association were giving a guarantee, though in truth the guarantee is a guarantee by some person unknown, and the words "the British Medical Association" at the bottom are a continuation of the sentence "the analyses of"—"the analyses of the British Medical Association."

Other documents are put forward by the defendant which I will not take up time by considering. It is, to my mind, beyond all question that both at 186, Walworth Road, and at High Street, Borough, the defendant, by his fascia, by the printed matter placed in his window, by the cards which he places behind the bottles, and by the labels on the bottles, is intending the public to draw the conclusion that these two shops are carried on by or in some connexion with the British Medical Association. I should have come to that conclusion without the evidence as to what the letters "B.M.A." mean in common parlance; but as a matter of fact it has been established that the letters "B.M.A." have meant in ordinary parlance for over twenty years past the British Medical Association. The evidence with regard to that was not cross-examined to for the most part. A dictionary of abbreviations by Mr. Rogers, published in 1913, has been produced in which the only meaning ascribed to "B.M.A." is "British Medical Association." A number of press cuttings have been produced from all sorts of papers referring to the British Medical Association as "B.M.A." The *Times* actually have at some previous date, which I have forgotten for the moment, under the heading "B.M.A.," "meaning the British Medical Association." I have not the smallest doubt that "B.M.A." to the public generally means the British Medical Association. That does not, of course, mean that every member of the public knows that fact; it means only that there are quite a large number of members of the public who do know the fact. Apart from that, the defendant, as I have said, has taken pains, by the arrangement in his shop windows and by reference to "B.M.A. Analysis," to make it perfectly plain that he meant by "B.M.A.," or intended the public to think was meant, "British Medical Association."

Now I shall deal very shortly with the suggestion that the defendant adopted the letters "B.M.A." as indicating "Bushby," "Marsh," and the person named Atkinson, who for a few months was employed at a salary by the company wound up in 1926. I have already pointed out that the company was formed for the purpose of carrying on the business of exploiting, so to speak, the analyses made by the British Medical Association. The defendant is described in the Articles of Association as a manufacturing chemist. One of the other signatories was also a chemist. It is perfectly plain on the evidence that they knew, and must have known, that "B.M.A." meant to a chemist, or to a doctor, or to the public, "British Medical Association." Frankly, in my opinion, to suggest that "B.M.A." was taken from the three initials of Bushby, Marsh, and Atkinson, is an obvious and ridiculous untruth. I am perfectly convinced in my mind that "B.M.A." was taken to help the defendant or his company to exploit these analyses of the B.M.A. by trying to represent to the public some association with the British Medical Association. Accordingly, I am quite convinced, upon the evidence before me here, that the defendant, prior to the date of the writ, was carrying on business at the two places I have mentioned so as to represent to the public that both those businesses were either carried on by the British Medical Association, or were in some way connected with that Association as businesses in which they had an interest of some kind.

The real question that falls to be decided here is the question of law whether, on that finding of fact, the plaintiffs are entitled to an injunction. No actual damage has been proved, or is suggested as having occurred. The action is in the nature of a *quia timet* action, and has to be dealt with on that footing.

After reviewing the decisions of a number of cases cited on behalf of the defendant and the plaintiffs, and the recent judgement of Mr. Justice Farwell in the action of British Legion v. British Legion Club (Street) Limited, his lordship concluded:

In the present case I find, as an inference of fact, that the acts of the defendant tend to injure the plaintiffs in their business both by tending to cause existing members of the Association to leave the Association and to cause qualified medical men not yet members of the Association to abstain from joining. The plaintiffs as a corporation have, in my opinion, a business: they subsist on subscriptions, and mainly on subscriptions of persons who become members. They are a purely voluntary body, and anybody may leave the Association or join it as they will. I am satisfied that people who may see these shops may come to the conclusion, and ordinary members of the public will come to the conclusion, that the British Medical Association is in some way connected with these shops. I have given my reasons for coming to that conclusion. Accordingly, my opinion is that the acts of the defendant tend to injure and to cause damage to the plaintiffs in their business, and that as a matter of law that is sufficient ground for granting an injunction in the present case. I am not relying on the likelihood of actions being brought against the plaintiffs if for some reason the remedies sold by the defendant turn out noxious or cause damage, but I do not wish to intimate any doubt on the view expressed by Mr. Justice Byrne in the case I have referred to of Walter v. Ashton upon such a point. My decision is that the plaintiffs are entitled to the injunction. . . . The defendant must pay the costs.

The Services

HONORARY PHYSICIAN TO THE KING

Surgeon Vice-Admiral R. St. G. S. Bond, C.B., M.B., C.M., F.R.C.P., F.R.C.S.Ed., D.P.H., has been appointed an Honorary Physician to the King as from July 1st, 1931.

DEATHS IN THE SERVICES

Inspector-General Charles Henry Woods, C.B., C.V.O., K.H.P., R.N. (ret.), died at Alverstoke on June 3rd, aged 90. He was born on May 20th, 1841, was educated at St. George's, and took the M.R.C.S. and the M.D.St. Andrews in 1862. Entering the Navy in 1862, he was promoted to staff surgeon in 1876, and to fleet surgeon in 1884. In 1875 he served on H.M.S. *Serapis*, which took the Prince of Wales, afterwards Edward VII, to India, for his tour there, the first visit of a member of the Royal Family to India. In September, 1878, he was appointed medical officer of the Royal yacht *Osborne*, Queen Victoria's favourite vessel, an old paddle steamer; and in 1878 was transferred to the *Victoria and Albert*, the successor to the *Osborne*. He was promoted to deputy inspector-general in 1895, and to inspector-general in 1900, but continued to serve as medical officer of the Royal yacht till his retirement, on attaining the age of 60, on May 20th, 1901. He received the C.V.O. in 1901 and the C.B. in 1902, and in 1901 was also made honorary physician to the King.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

At the House of Commons, on July 15th, a conference was held on the Proprietary Medicines Bill, which was attended by representatives of the Pure Food Council, the British Medical Association (Dr Alfred Cox), the Pharmaceutical Society, and the Proprietary Medicine Manufacturers Sir Robert Newman was in the chair, and Mr Somerville Hastings, who introduced the Bill, attended The meeting agreed to arrange a round-table conference of all interests to see if an agreed Bill on the subject could be presented to Parliament The Proprietary Medicine Manufacturers intimated that they object to the proposed deposition of formulas and to the schedule of diseases which, under the present Bill, may not be treated by proprietary medicines

The House of Commons this week read the Unemployment Insurance Anomalies Bill a third time. Debates arose on agriculture, transport, and other services Progress has been made with the Bethlem Hospital Amendment Bill, which received its second reading in the Commons on July 17th

Mental Deficiency

Replying to Major Church, on July 16th, Mr LEES SMITH said that, on March 31st, 1930, there were 15 500 children under instruction in England and Wales in special schools for the mentally defective , 27 per cent of the local authorities in England and Wales provided such special schools Attendance was compulsory up to the age of 16 Children certified as suitable for education in special schools for the mentally defective suffered from a severe degree of retardation, or incomplete mental development There were no separate statistics in regard to children suffering from "known mental diseases," unless severe retardation itself was so regarded, but they were few in number, and usually fell outside the scope of the educational system Records of after-careers were kept as far as possible by the local education authorities and voluntary bodies which maintained special schools

Replying to Mrs Manning, on July 16th, Mr LEES-SMITH said that the number of local authorities who approached the Board of Control about the provision of special schools for mentally defective children and were advised not to proceed was one in 1926 eight in 1927 two in 1928, and one in 1929 Since January 1929, the Board had approved any proposals submitted The refusals were made under a previous administration and the reason was that the report on mental deficiency was being prepared

Miss LAWRENCE, replying to Mr G MacDonald on July 20th, said that on January 1st, 1926 there were 3,581 mental defectives in certified institutions in Lancashire and 12,766 in England and Wales In 1927 there were 3,627 such persons in Lancashire and 13,342 in England and Wales The figures for 1928 were 3,712 and 14,099 respectively , for 1929, 3,770 and 14 840 , for 1930 3,858 and 15,664 , and for 1931, 3 949 and 17,200 Separate statistics for children were not available, but it was estimated that of the numbers above approximately 15 per cent were children under 16 years of age

Sterilization of Mental Defectives

In the House of Commons, on July 21st, Major CHURCH asked leave to bring in a Bill to enable mental defectives to undergo sterilizing operations or sterilizing treatment upon their own application, or that of their spouses, parents, or guardians [The text of this Bill will be found at page 161] He said that those associated with him realized that they were asking the House to do something which could be regarded as being in advance of public opinion His own view, though it was not that of all those associated with him, was that this was merely a first step in order that the community might be able to make an experiment on a small scale before compulsory sterilization proposals for unfit persons were put forward The Bill was based on the willingness of those suffering from mental defect to undergo voluntarily an operation which would prevent them bringing children into the world It provided every reasonable safeguard for the voluntary principle The patients themselves must consent to the operation, and then their spouses or parents or guardians must agree There must be consent on the part of the Board of Control, and, finally, the operation could only be carried out after approval had been given by a judicial authority The operation would not be the mutilation usually associated with sterilization It might be urged that mere sterilization was not enough, and was not a cure for the problem of mental disease He did not suggest that it was , but he suggested that, since information compiled about the ancestry of mental defectives in a number of different States and countries showed that anything from 45 to 80 per cent of the mental defectives had inherited defective germ plasm, it would be advisable to take the risk of sterilizing all the defectives, and that in the course of a generation or so their number could be reduced to measurable size

Dr MORGAN asked the House not to approve what he said was anti-working class legislation Nature had its own way of dealing with mental defectives—by limiting their progeny (Cries of "No") There was defective germ plasm in every family, and it was computed that the chance of a defective paternal and maternal plasm uniting was one in five million The sterilized defective would spread venereal disease He advocated the alternative of segregation

The motion for leave to introduce the Bill was rejected by 167 votes to 89.

Housing

In the House of Lords, on July 13th, the BISHOP OF SOUTHWARK called attention to the number of persons who in London and elsewhere, lived in underground dwellings He asked how many houses the local authorities proposed to build in the next five years He said that the medical officer of health of the London County Council had stated that there were about 30,000 basement dwellings in London unfit for human occupation in which 100 000 persons were living These places were always damp and dreadfully overcrowded The results to health were deplorable He (the Bishop) was told that basement children were unhealthier than slum children and that they suffered particularly from pneumonia and rheumatism Lord JESSEL said that one difficulty to be contended with was that tenants would not move because they feared to lose the protection of the Rent Restrictions Act Lord DICKINSON said his information was that things were getting worse rather than better

Lord SNELL said that the Government were in complete agreement with the main principle of the Bishop of Southwark's speech The powers possessed by local authorities were adequate to deal with the problem They already possessed full powers to close unhealthy dwellings The Housing Act of 1930 was an earnest of the Government's intention to deal drastically with the whole problem of the slums They would keep the local authorities alive to their duties.

Puerperal Fever

On July 16th, in reply to Mr Ramsbotham, Mr GREENWOOD said he understood that a new serum was being used for the treatment of puerperal fever in this country It was not yet possible to arrive at any definite conclusions on its value Research into the causes and treatment of puerperal fever was being undertaken with the assistance of the Medical Research Council and his Department He did not consider there was any necessity for a special commission of inquiry

Replying to Mr Sorensen, on July 16th, Mr GREENWOOD said that separate figures for nursing homes were not available , but, according to the returns furnished by medical officers of health, the numbers of maternal deaths which occurred during 1930 in all institutions including nursing homes, in Essex, Middlesex and Kent, were 68 53, and 34 respectively No corresponding figures were available for the first six months of 1931

Lead Poisoning.—Mr CLYNES told Mr Graham White, on July 16th, that the number of cases of lead poisoning notified during 1930 under the regulations of the Lead Paint Act was sixty-six, of which thirteen were fatal He had no reason to doubt that the regulations were working satisfactorily but would receive information of instances where they were not

Obituary

F RICHARDSON CROSS, LL D, M B, F R C S

Consulting Ophthalmic Surgeon, Bristol Royal Infirmary, and Bristol Eye Hospital

As announced in our last issue, Mr F Richardson Cross, the well known ophthalmologist, died at the age of 83, on July 12th, at his residence, Worcester House, Clifton, Bristol. He had been in good health until a few weeks ago when he was attacked with influenza, from which he did not recover, although his death had not been anticipated. In the past few years his activities had of necessity been curtailed, but he nevertheless maintained a keen interest in many spheres besides that of his own specialty the active practice of which he only gave up in the last three years of his life. Even at the age of 78 he was operating with his accustomed skill and steadiness.

Francis Richardson Cross was a Somersetshire man, having been born at Merriott, where his father, the Rev. Joseph Cross, M.A., formerly precentor of Bristol Cathedral, was vicar. Educated at Crewkerne Grammar School, he went up to King's College, London, where after qualifying, he acted as house surgeon in charge of the eye wards, subdean, medical tutor and lecturer and was associated with the late Lord Lister, and in later years was elected a Fellow of the College. After taking his F.R.C.S. in 1878, he left London, and was elected assistant surgeon to the Bristol Royal Infirmary in September of that year, and became surgeon in the following January. This post was held until October, 1885, when he was elected ophthalmic surgeon. Although greatly interested in diseases and injuries of bones during these years he had realized what a wide scope lay in the study and practice of ophthalmology, and of the necessity of an ophthalmic department in the Royal Infirmary. Accordingly he decided to devote himself to the special subject in which, as time went on, he was to become so prominent a figure, and, founding the department at the Infirmary, acted as its surgeon until July, 1900. His association with the Infirmary was not, however, confined to this one subject, for he was interested in its work generally, and in medical education in particular. In 1880 he was appointed dean of the Medical Faculty of University College, Bristol—a new post formed to supervise and arrange clinical instruction. His work with the Infirmary did not cease until September, 1928, and throughout these years he gave of his best towards the management of its affairs, as a small recognition of which he was elected a vice-president in 1919. There is no doubt that Mr. Cross, by his wise advice, ability, and powers of organization, advanced the welfare of the Infirmary in a high degree, and as a prominent member of its committee said, "his personality had been a spell upon the institution, and stood therein for happiness, love of work, and duty, which had also affected the staff as a whole."

In 1882 Mr. Cross was appointed honorary surgeon to the Bristol Eye Hospital, and it was here, even more than at the Royal Infirmary, that his chief work in ophthalmology was done. The hospital was then in a poor state owing to lack of support, but throwing his indomitable energy into the task, it was not long before striking improvements were effected, and it is almost wholly due to him that the hospital has reached the state of efficiency and prominence that it now holds. His first house surgeon was the late Professor Snellen of Utrecht, son of the able ophthalmologist whose name is associated with the test types, and following him comes a long list of men, all of whom realize the privilege of having worked under him, and are correspondingly grateful for his able teaching and example. He was a man who had set himself a very high standard of life, and he expected it in those who were associated with him. His active work at the Eye Hospital was continued until some five years ago.

In 1894 Mr. Cross was president of the Ophthalmic Section of the British Medical Association at its Bristol meeting, and was Bradshaw Lecturer at the Royal College of Surgeons of England in 1909. In 1913 he was elected president of the Ophthalmological Society of the United Kingdom, and vice-president of the Ophthalmic Section of the International Congress of Medicine, held that year in London. In 1915 he delivered the Long Fox Lecture at Bristol, and in 1920 was Doyne Memorial Lecturer at the Oxford Ophthalmological Congress. He was elected a member of the Council of the Royal College of Surgeons in 1898, and of the University of Bristol from 1909 to 1912, in which also he was reader in ophthalmology. In addition, he had a seat on the council of Clifton College from 1900 to 1927.

His interests were very wide, and besides his professional achievements he was a very prominent citizen of Bristol. In 1897 he was elected sheriff of the city and justice of the peace, and to commemorate the birth of a daughter in that year was presented with a silver cradle. In 1889 he was president of the Bristol Grateful Society, and of the Bristol Dolphin Society in 1912, and in 1916 of the University Colston Society. During his tenure of these offices he was instrumental in collecting large sums for charitable objects. He acted as chairman for the Bristol centre of the St. John Ambulance Brigade, and for very many years was chairman of the Bristol School of Industry for the Blind. The welfare of the blind was a matter which Mr. Cross had very much at heart, and on behalf of those unfortunate ones who had lost their sight his labours were unceasing. He was instrumental in obtaining new and better premises for the Royal School for the Blind, and helped to establish a blind women's hostel in the city.

Standing well over six feet in height, with good breadth of shoulder, fine upright carriage, and, for most of his life, white or nearly white hair, Mr. Cross was an impressive figure. He was one who in any gathering at once arrested attention. He was a fine speaker with the gift of being able to say the right word at the right moment, and with a cultured charm which always won approbation. The writer of this, one of his old house-surgeons, feels that it is impossible to pay in words an adequate tribute to him, to attempt to convey quite what he was to those who had the privilege of working with him. At first he seemed to inspire only awe and respect, but on closer association these feelings passed to love and admiration for a great souled man. In his life

he accomplished much for the community, and his influence in many spheres was great, but not the least of these is that which has impressed itself upon his old alumni practising all over the world.

In 1889 he married Eva, daughter of Captain Hawkes, R.N., who predeceased him in 1920, and he leaves three daughters. The funeral service took place on July 16th in Bristol Cathedral, and, besides the principal mourners, there were present many prominent people, together with representatives of learned societies, professional and otherwise. B. C.

Sir RICHARD CRUISE has been good enough to send the following appreciation. A few biographical details included above have been omitted.

The announcement of the death of Mr. Richardson Cross in the daily papers will have produced a sensation of deep regret and great personal loss among a very wide circle of patients and friends. His reputation as an oculist of keen discernment, shrewd judgement, and deft execution was far-flung at the beginning of this century. He was a man of very fine presence, an erect and athletic carriage, and a commanding personality, expressive of kindliness combined with courteous determination; an enthusiast in all things, but primarily in ophthalmology. He was a vital factor in the professional and civic life of Bristol for the best part of fifty years.

While holding the post of medical tutor and subdean at King's College, he was clinical assistant at the Royal London Ophthalmic Hospital, and was frequently in charge of the eye department at King's College Hospital. His work at King's brought him into association with Lister, who exerted a profound influence on his whole career, and it was at Lister's express wish that he accepted the invitation to join the Bristol Medical School, and was the first exponent of Lister's teaching of antiseptic surgery in the West of England. One of Mr. Cross's proudest possessions was the following testimonial in connexion with the Bristol appointment, signed by Lord (then Mr. Joseph) Lister, dated August 4th, 1878:

"Since my connection with King's College I have been constantly thrown into intimate relations with Mr. Cross. I have found him not only well versed in professional knowledge but earnest and unprejudiced in the further pursuit of it. I believe Mr. Cross would prove a great gain to any medical school with which he might become connected."

In later years, when the prognosis had long been verified, Cross was elected to the Council of the Royal College of Surgeons of England, at his first attempt, and his candidature for election was proposed by Lord Lister.

In 1882 he became surgeon to the Bristol Eye Hospital, and it is with that institution that his name will be enrolled in perpetual honour. With enthusiastic determination he raised funds and converted a collection of mean and ill-equipped dwellings into a well-appointed up-to-date institution. A long succession of house-surgeons can bear testimony to the energy of his initiative for the furtherance of the welfare and treatment of all who attended the Bristol Eye Hospital. He played an important part in the foundation of Bristol University, was awarded the honorary degree of LL.D., and his portrait hangs in the council meeting room. In the civic life of Bristol his name was a household word.

As a young man he was an exceptional all-round athlete, a fine runner at the United Hospitals meeting, and captain of King's College Football Club. Always a keen horseman, he hunted regularly up till the war with the Duke of Beaufort's and Berkeley Hounds, and was justly proud of being given the hunt "button" by the late Duke of Beaufort, and of wearing the "blue and buff" in the hunting-field. He kept a pedigree herd of shorthorns at his hunting-box at Alverston, bred blood-stock with which he won some good races at Newmarket, trained and raced carrier pigeons, and was president of the Bristol Kennel Club.

In an address some years ago he foretold the formation of the Ministry of Health in these words: "The medical profession must in the future be bold enough to advise the State as well as the family concerning conditions of life, labour, and environment." He maintained that, for his own salvation, a man should not allow his profession to exclude his active interest in other spheres of life, and lived up to his conviction.

His interest, help, and guidance to those who worked for and with him were generous and genuine, and as one who had the good fortune to be of that company, and on behalf of the remainder of that company, I submit this inadequate tribute of our appreciation.

ROBERT E. LORD, M.D.

Consulting Physician, Colwyn Bay and West Denbighshire Hospital

We regret to announce the death, on July 10th, of Dr. R. E. Lord, who was one of the most prominent citizens of Colwyn Bay, and was regarded as the head of the profession in that district. He was born at Rochdale on January 11th, 1867, and was educated at the Manchester Grammar School and Owens College, Manchester. Although in his early years he had a delicate constitution, he was a brilliant student, and passed the B.Sc.Lond. with honours in physiology when he was only 18 years of age. He graduated M.B. Lond. when he was 23, and M.D. in the following year. He had also obtained honours in anatomy and materia medica at the intermediate M.B. examination. He then served as house-physician to the Manchester Royal Infirmary and senior house-surgeon to the Salford Royal Hospital, and was an assistant demonstrator of anatomy at Owens College.

Dr. A. N. LEEMING writes:

When Dr. Lord came to Colwyn Bay in 1893 he was in delicate health, having had pneumonia with complications, and it is marvellous to think that he has laboured with such success and distinction and put through such a quantity of valuable work. This speaks well for the renovating capacity of the North Wales coast. During his early years he was one of the surgeons to the old Colwyn Bay Cottage Hospital, and was one of the principal supporters of the movement to enlarge this institution into the Colwyn Bay and West Denbighshire Hospital. At the same time, most valuable work was done by the old hospital, especially considering the limited number of beds available. Dr. Lord for many years was an authority on the treatment of tuberculous disease, and the results of his great experience were given in a valuable treatise read to the Colwyn Bay Medical Society a few years ago. At the time of his death he was consulting physician to the Colwyn Bay and West Denbighshire Hospital and chairman of the Medical Advisory Board, and was also president of the Colwyn Bay Medical Society and a member of the North Wales Branch Council of the British Medical Association. Dr. Lord also found time to do valuable work outside his profession. He was the people's warden at St. Paul's Church, a member of the executive committee of the Colwyn Bay Guild of Social Service, and a justice of the peace for Denbighshire since 1917. At the time of his death he was the only doctor in practice in Colwyn Bay serving on the bench of magistrates. As an indication of his prestige in Manchester, it may be noted he was one of the four vice-presidents of the Manchester Royal Infirmary Residents' Club, and the only one of the four who was not a consultant in Manchester. For many years he had held the responsible position of medical officer to Rydal School, and partly in consequence of this his

name is well known all over the country It is difficult to exaggerate his value to our hospital, at every stage in its evolution he has taken a valuable and influential part His judgement and advice on committees and the hospital board have been universally respected and supported, when serving on the constitutional committee of the new hospital his opinions were of the utmost value in framing the rules which guide the running of the institution

Dr Lord was an example of the finest type of medical man, he was devoted to duty, and animated with a high minded loyalty to the best traditions of his profession, he was kind, courteous, and skilful He was so keen on his work that the latest advances were always noted and studied by him, consequently he was often called in as a second opinion, on which occasions his advice was always valuable to his colleague and his remarks to the patient helpful and inspiring He had a keen sense of humour, and on occasions showed signs of great determination, these qualities were very useful sometimes when he was chairman of committees He leaves a widow, two sons, and three daughters, and with them the deepest sympathy of the whole neighbourhood is felt His wife has devotedly supported him in many charitable and public spirited movements His eldest son was killed during the war, his second son, Herbert, is in practice with his father's firm

Dr E L B WILKES writes

Dr Lord was generally expected, after his brilliant studentship to remain in Manchester as consultant His career was, however, interrupted by a severe illness, after which he came to Colwyn Bay to recuperate—and stayed He was a complete general practitioner, but he was much more He was the pioneer of modern major surgery in the district and his surgery showed the same thoroughness of knowledge, sound judgement, and conscientious completeness in practice as marked all his other activities Yet it was as a physician that Dr Lord chiefly made his name, and his reputation in treating diseases of the lungs especially tuberculosis, was widespread, and had much to do with the growing reputation of Colwyn Bay The range and accuracy of his knowledge in all branches was remarkable If he could be said to have specialized, it was in affections of the respiratory tract—from anterior nares to alveoli But the standard of his work in everything was really that of the "specialist" He became an extremely busy man but his methodical habits carried him through and he always made time to keep himself well abreast of medical progress All his work was of the same high standard, for rich or poor, in hospital or private practice—there was no slap dash "take it easy" "it'll do" about him His skill and judgement were always at the disposal of his colleagues, freely and generously His influence greatly helped to promote friendly relations and co operation, and his fairness and his careful weighing of all questions submitted to him were of the utmost value He was, as it were, a father to us

---

In quick succession two old St George's men general practitioners of the best type in the West End of London, have passed behind the veil—E B Turner on June 30th in London, and after two months' illness, MONTAGU MONIER WILLIAMS on July 4th at Collioure, Pyrenees Orientales, France, where he had lived in retirement since 1927 They both had wide interests and were prominent in directions other than those of private practice, and especially in different forms of sport Montagu Sneade Faithfull Monier Williams was born at Cheltenham on September 19th 1860 as the fifth son of Sir Monier Monier-Williams KCIE, Boden Professor of Sanskrit at Oxford from December 1860, to 1887 and his wife, Julia Greatham daughter of the Rev F J Faithfull, Rector of Hatfield, Herts Educated at Winchester, Christ Church, Oxford, and St George's Hospital, he qualified at the Conjoint Board in 1890, and, marrying in the same year practised in Onslow Gardens for the whole of his professional life After the war he took an active part in carrying out in London the methods of Emile Coué, whom he visited at Nancy, where the new therapeutic treatment by auto suggestion had superseded the hypnotic suggestion practised by A A Liebault and H Bernheim in the last quarter of the last century He induced Coué to come to England to demonstrate his methods gratuitously, was physician to the Chelsea Clinic of Psychical Education, and had an auto suggestion clinic free to the poor in King's Road, Chelsea His first wife died in 1925 after a long illness, and two years later he married again, the widow of Warington Baden Powell, KC, and retired to live at the Chateau de Collioure in the South of France, where he was much interested in growing vines Like his father he was an expert skater, and wrote authoritatively on the subject *Combined Figure Skating*, with his brother Stanley (1883), *Figure Skating Simple and Combined*, with W R Pidgeon and A Dryden (1892), the volume in the Isthmian Library (1898), and the article in the *Encyclopaedia of Sport* (1898) He invented and patented the Monier Williams skate During this century he became a first class croquet player, and competed at a number of meetings sometimes under the sheltering pseudonym of "A S Kator" A modest and upright gentleman he leaves many friends, among them the writer, who knew him for sixty years, to sympathize with his widow in an irreparable loss

---

Dr JAMES MATTHEW LAZENBY, who died at his residence in Jersey on June 5th, after a long illness, at the age of 68, received his medical education at Newcastle, where he won several scholarships and prizes He graduated MB of Durham University in 1885 and BS two years later After spending some years at Long Preston, Yorkshire, he commenced general practice at Whitley Bay in 1896, and for several years was medical officer to the Northumberland Village Homes and the Prudhoe Memorial Convalescent Homes In 1909 he removed to Gosforth, and subsequently to Jersey, where he built up a large practice and became widely popular At the outbreak of war he obtained a temporary commission in the RAMC, and, after service in France, went to Salonika He had an arduous time in the hospital ships *Panama* and *Esquito*, and was eventually invalided from the Service Apart from his medical work Dr Lazenby took particular interest in social evolution, and especially in religious developments He published a treatise entitled *A Layman's Religion*, in which he outlined the religious aspirations of the average man In the earlier part of his career he devoted much time and energy to promoting instruction in ambulance work, and helping the organization of local nursing associations At his funeral on June 8th there was a large attendance of his personal friends and representatives of various institutions and societies in Jersey

---

To the deep regret of his many friends and patients, DAVID SOMERVILLE DOUGHTY passed away at Dalston, Cumberland, on July 10th Born at Thornhill, in Dumfries in 1863, educated at Hutton Hall in the same county, he became in due course a medical student at Edinburgh University, where he graduated MB CM in 1886, proceeding to his MD degree in 1895 He began his medical career as house surgeon to the Dumfries Infirmary, spent a year as an assistant in London then practised for another year at Hesket Newmarket in Cumberland, before starting in practice at Dalston where he spent the remainder of his life He retired from active work only a few weeks ago owing to failing health A colleague writes Of Dr Doughty as a man and a physician it is difficult to speak too highly He was the type of man eulogized by the Roman poet of old, *integer vitae scelerisque purus* With a keen interest in his profession and an abundant store of human sympathy, he was one of the finest specimens of the old fashioned

country doctor one could wish to meet. He had many and varied interests. He was not only a popular doctor; he was a keen follower of hounds, an ardent fisherman, and a first-class game shot, and there was no project set on foot calculated to promote the happiness of his neighbours which had not his whole-hearted support. Among his other activities he found time to serve for many years as chairman of the Local Panel Committee of the National Insurance. The meetings of this body he presided over with rare business acumen, while his genial good humour soon smoothed down any asperities arising in the course of the discussions. A sad circumstance in connexion with Dr. Doughty's death is that he was about to be presented with an illuminated address and a substantial testimonial from the clientele he had so faithfully served for forty-two years. We feel sure that many years will have passed away before the memory of this beloved physician fades from the minds of those who knew him and appreciated his worth.

The following well-known foreign medical men have recently died: Dr. OTTO SCHWARZ, extraordinary professor of ophthalmology at Leipzig, and editor of an encyclopaedia of ophthalmology; Professor MAX LANDOW, formerly director of the surgical division of the municipal hospital at Wiesbaden, aged 74; Dr. OTTO WALLACH, professor of chemistry at Göttingen, aged 84; Dr. ANDRÉ SOREL, a Paris radiologist; Dr. HIRAM WOODS, emeritus professor of ophthalmology at the University of Maryland School of Medicine, aged 73, of pneumonia; Professor F. KERMAUNER, head of the Second University Women's Clinic in Vienna, and author of works on carcinoma of the uterus, malformations of the female genitalia, and ovarian tumours, aged 58, of influenza; Dr. AUGUSTE ROUD, professor of anatomy at Lausanne, aged 60; Dr. RUDOLF WANACH, formerly professor of surgery at Dorpat, aged 69; Dr. EMIL VILLINGER, extraordinary professor of neurology at Basel, and author of a work on the brain and spinal cord, aged 61; and Dr. ABRAHAM PÉREZ MIRO, professor of therapeutics at the Havana School of Medicine.

Universities and Colleges

UNIVERSITY OF OXFORD

At a congregation held on July 18th the following medical degrees were conferred:

M.CH.—T. H. Sellors, B. G. Scholefield.

B.M.—G. H. Bateman, F. Bicknell, H. de B. Kempthorne, R. B. Scott, T. R. Plummer, H. S. Atkinson, R. D. Newton, R. R. Bomford, Elizabeth C. M. Brunyate, Olive M. Capper Johnson, Mrs. Winifred Pitkin.

UNIVERSITY OF CAMBRIDGE

The managers of the Frederick James Quick Fund have elected Mr. David Keilen, M.A., F.R.S., Magdalene College, to the Quick Professorship of Biology for three years from November 1st, in succession to Dr. G. H. F. Nuttall, who retires on October 31st. Professor Nuttall has held this chair since its foundation in 1906.

UNIVERSITY OF LONDON

The Rogers Prize of £100 has been awarded to R. W. Fairbrother, M.D.

UNIVERSITY OF DURHAM

At the convocations held on June 30th and July 1st the following degrees and diplomas were conferred:

M.D.—C. F. Fairlie, G. McCoull, L. F. O'Shaughnessy (*in absentia*), T. S. Severs, G. E. Stephenson, H. G. Ungley, A. H. Wear, J. H. Weir.

M.D. (PRACTITIONERS).—J. W. Irvine.

M.B. AND B.S.—H. Bannerman, W. C. D. Bewick, R. Bewley, J. I. M. Black, T. H. Boon, Gladys M. Brice, J. L. Burn, C. F. Down, W. P. Dunn, W. L. Gardner, J. W. Gibson, J. Giles, T. R. Harlan, H. F. Harvey, N. V. Hepple, A. R. Holtby, A. D. Kelly, J. J. H. Lowe, Elizabeth S. Malcolm, Eileen G. Marshall, J. A. McKeon, J. C. Moor, E. W. Peet, A. H. Penman, A. de W. Ranken, L. R. Routledge, Kathleen Rowstron, E. Smith, H. K. Vernon.

B.HY. AND D.P.H.—B. Sergeant.

UNIVERSITY OF LEEDS

Department of Obstetrics and Gynaecology

The following elections to chairs in the Faculty of Medicine have been made by the council of the University of Leeds: Mr. W. Gough, B.Sc., M.B., B.S., F.R.C.S., as professor of gynaecology; and Mr. A. M. Claye, M.D., F.R.C.S., L.R.C.P., as professor of obstetrics.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

At the last meeting of the Royal Faculty of Physicians and Surgeons of Glasgow the following were admitted, after examination, as Fellows of Faculty: Amar Chand Bhardwaj, M.R.C.S., L.R.C.P., John Aloysius McCann, L.R.C.P. and S.Ed., L.R.F.P.S.G., and William Patrick, M.B., Ch.B.

Medical News

To mark the centenary of Hanwell Mental Hospital, which was first opened in May, 1831, the Minister of Health had consented to open, on Wednesday, July 29th, at 3 p.m., a new admission hospital villa, recently erected at the hospital.

St. Bartholomew's Hospital old students' annual dinner will be held on Thursday, October 1st, at 7.30 p.m., in the great hall of the hospital, with Sir Percival Hartley in the chair. The honorary secretary is Mr. R. M. Vick, F.R.C.S., 113, Harley Street, W.1.

The Fellowship of Medicine and Post-Graduate Medical Association announces that, from August 4th, continuing through the month, a course in urology will be held at the All Saints' Hospital; fee, £2 12s. 6d. The Queen's Hospital for Children will undertake an all-day course from August 17th to 29th, instruction being entirely by demonstration of cases, medical as well as surgical; lunch and tea are provided by the hospital authorities; fee, £2 2s. The Brompton Hospital will hold a course from September 7th for one week, the Bethlem Royal Hospital from September 8th to October 3rd, the Infants Hospital from September 14th to 26th, the Central London Ophthalmic Hospital from September 14th to October 10th, the Westminster Hospital from September 14th to 26th, and the Metropolitan Hospital from September 28th to October 10th. Detailed syllabuses may be obtained from the Fellowship, 1, Wimpole Street, W.1. (Langham 4266).

The British Red Cross Society will hold a course of nine lectures and demonstrations on tropical hygiene and nursing, commencing on Monday, September 28th, at 5.30 p.m. It is intended for persons who are going to warm climates for the first time. Particulars may be obtained from the county secretary, 9, Chesham Street, Belgrave Square, S.W.1.

Dr. Henry E. Sigerist, professor of the history of medicine at Leipzig, has been invited to give a series of lectures at the Johns Hopkins University, Baltimore, and various other universities in the United States.

As already announced in these columns the third International Congress of Radiology will be held in Paris from July 26th to 31st, with Madame Curie as president of honour and Dr. Antoine Béclère as executive president. All meetings will take place in the amphitheatres of the Sorbonne, Rue des Ecoles. Details of the programme will be found in the May issue of the *British Journal of Radiology*.

The thirty-first Congress of the French Association of Urology will be held at Paris under the presidency of Dr. Gauthier of Lyons on October 6th, when the subject for discussion will be renal acidosis, introduced by Drs. Chabanier of Paris and Lobo-Onell of Santiago. Further information can be obtained from the general secretary, Dr. Pasteau, 3, Avenue de Villars, Paris, 7e.

The Medical Society of Davos is arranging an international conference on tuberculosis, to be held from October 5th to 10th.

The Ministry of Health has issued a circular (No. 1206) dealing with the contents and arrangement of the annual reports of medical officers of health for 1931. In view of the alterations made by the Housing Act, 1930, a revision of the headings under which housing statistics have been given in recent years has now become necessary. Instructions are given in regard to the accurate filling up of forms, together with suggestions for recording action taken under the Prevention of Tuberculosis Regulations, or under Section 62 of the Public Health Act, 1925.

A special supplement to the issue of *Nature* for July 18th contains an article by Sir James Jeans, headed "The annihilation of matter," being the substance of ectures delivered before the Universities of Princeton, Yale, and Harvard, under the auspices of the Franklin Institute of Pennsylvania.

The July issue of the *Leprosy Review*, the quarterly publication of the British Empire Leprosy Relief Association, is devoted more especially to a report of the Leonard Wood Memorial Conference on Leprosy, which was held in Manila, Philippine Islands, from January 9th to 23rd. A memorandum contributed by Sir Leonard Rogers to that conference, on the present position of prophylaxis against leprosy in relation to recent improvements in treatment, is published in an abridged form. Compulsory segregation is condemned, but Sir Leonard Rogers admits that compulsion may be useful in the case of those with early disease who refuse to attend for regular treatment, and for patients with open lesions who are unable, or unwilling, to adopt the necessary precautions. Dr. P. Manson-Bahr continues his account of quinine therapy in malaria.

The council of the International Society of Medical Hydrology has published a register of spas and medicinal waters, which has been compiled by its Standard Measurements Committee. The register is designed to promote the regularizing of data regarding spas and medicinal waters in all parts of the world, and is obtainable from the office of the society, 55, Wellington Road, N.W.8, or from Headley Brothers, 109, Kingsway, W.C.2, price 1s. net.

The following promotions in, and appointments to, the Venerable Order of the Hospital of St. John of Jerusalem are announced:—Knights of Justice: Sir James Purves-Stewart. Knights of Grace: The Hon. Murray Maclaren, M.D. (New Brunswick). Commanders: Sir Thomas Houston, Dr. E. A. Chill, Sir Percival Horton-Smith Hartley, Dr. Henry John Barnes, Dr. Richard Clegg, Dr. F. N. Kay Menzies, Surgeon Vice-Admiral Sir Arthur Gaskell, the Hon. J. H. King, M.D. (Ottawa). Officers: Dr. G. E. Peacock (Johannesburg), Dr. George Mackie, Dr. A. C. W. Knox, Dr. W. Egbert Thomson, Surgeon Commander R. J. G. Parnell, R.N., Sir Squire Sprigge, M.D. Serving Brothers: Drs. W. Lee, Leonard A. Line, F. Stanley Booth, Leslie Fetherston, C. A. Verco, W. G. Shellshear, W. B. A. Moore, D. H. Griffiths, L. R. E. Downer, and Lieut.-Colonel G. C. E. Simpson, R.A.M.C. Associate Serving Brothers: Drs. S. K. Engineer and D. H. Mehta. Serving Sisters: Sibyl C. Bevan, M.B., and Susanneh H. O. Reilly, M.B.

Dr. J. Goyanes and a committee of leading Spanish surgeons have formed the Madrid Surgical Society to encourage surgical research throughout the country and to raise the status of the profession. The new society proposes to encourage the formation of similar bodies in the provinces, and so prepare the way for a National Association of Spanish Surgeons.

Drs. Carlos Mario Cortezo, editor of *El Siglo Medico*, and for many years president of the Royal Academy of Medicine of Madrid, has been awarded the Golden Fleece prize, an honour hitherto only bestowed on kings, princes, and eminent politicians or soldiers.

Turkey, with a population of 13,000,000, possesses 3,509 medical practitioners, of whom 1,000 live in Stamboul, which has 714,000 inhabitants, and the rest chiefly in Anatolia, especially the larger towns such as Smyrna and Angora. The number of medical journals in Turkey amounts to 20.

Dr. Ribot, the head of the Health Service of Marseilles has been elected mayor of that city.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM* 9861, 9862, 9863, and 9864 (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:
EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Attiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Medisecra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS

Mammary Abscess

"*Suburban G.P.*" writes: In reply to Dr. Halford's letter concerning the etiology of mammary abscess, I am sorry I am unable to give any details concerning the presence of ophthalmia in the babies during the first two weeks of life. Their histories gave no support to your correspondent's suggestion, which, I may add, appears to be a fair possibility. I can only say that, during the past year, I have seen six cases, the mother in each instance being young, healthy, and free from any trace of lurking sepsis, and all of whom have had normal puerperia. No doubt, if my previous remark regarding the duration of the mothers' incapacity were taken literally, an unfavourable reflection on treatment would be justified; but Dr. Halford must remember that the cases referred to had to be dealt with under unsuitable domestic conditions and inadequate help, when worry and anxiety tend to become important factors in retarding convalescence. It is perhaps a curious reflection that among the poorer classes, where asepsis and cleanliness are a negative factor, mammary abscess, in my humble and limited experience, appears to be much less rife. In conclusion, I would like to express my thanks to Dr. Halford for the emphasis he has placed on the underlying surgical principles involved.

Painful Heels

"ELECTROTHERAPIST" asks for suggestions for treatment of any kind for a case of painful heels in a woman of 55. The pain is experienced directly in the centre and inner sides of the under part of the heels. They are a little tender and swollen, and the pain is increased by walking, and often severe on rising. Gonorrhoea can be excluded, and gout is improbable as no relief has been obtained by atophan, etc. *X*-ray examination shows a very small spur or plaque of (?) myositis ossificans between the tuberosities at the insertion of the plantar muscles. Diathermy, faradism, ionization, wax baths, etc., have been tried with very little, if any, success; also deep massage.

Tennis Blisters

"T. W. S." (Surrey) writes: Can anyone inform me of the best way of preventing blisters on the hands and feet of a lawn tennis player? I have tried treating them with industrial methylated spirit, and with a solution of potassium permanganate (1 in 2,000) in order to harden the skin, without success. Rubber adhesive plaster bound round the anterior arch of the feet is only partially successful.

June 4th. Presumably he will be satisfied if this is arrived at by taking two-twelfths of the year's assessment, but the authorities are entitled to have the liability more accurately measured according to the value of the "bookings" during that period. Unless the change in basis would make a substantial difference for those two months we think that the authorities are not likely to insist on such a revision. (*b*) As regards the year ending April 5th last (that is, 1930-31), the authorities have the option of revising the assessment for that year to the amount of the earnings of that actual year—the assessment was presumably on the amount of the profits of the year 1929-30. As for any period subsequent to June 4th, our correspondent is not liable to assessment in respect of receipts from the practice he has given up; they represent accumulations of earnings on which he has accounted for his liability to tax.

Car Transactions

"F. G." bought a new E car in March, 1925, for £275; in June, 1930, he sold it for £68 and bought a second-hand 21 h.p. R car for £110; in February, 1931, he sold that car for £50 and bought a second-hand 16 h.p. A car for £165. He does not claim depreciation allowance.

*** In our opinion, and especially in view of the short time the R car was held, the two transactions should be regarded as one, and the allowance claimed for upkeep of equipment should be (£110 − £68) + (£165 − £50)—that is, £42 + £115 = £157. If, however, "F. G." makes his accounts up to December 31st each year, he is faced with the difficulty that the two transactions fall in different years as far as the calculation of his profits is concerned. In that case he can undoubtedly claim £42 as an expense of the year 1930, but the inspector of taxes may object to allowing £115 for 1931 on the ground that the transaction by itself resulted in an improvement, and was therefore partially a capital transaction. In view of the obvious equity of "F. G.'s" case, however, he may not press that technical objection. It would clearly have been better for "F. G." to have claimed depreciation and obsolescence allowance.

Cash Basis and Car Renewal

"M. O. R." inquires: (1) whether the tax authorities can insist on bringing unpaid book debts into the calculation of his liable earnings, and (2) what allowance he can claim for the exchange of a car (bought when new for £162) for a second-hand car at a cost of £75 net.

*** (1) The authorities are technically correct, but usually accept a cash receipt basis unless the income of the practice is increasing. If there is no such increase "M. O. R." might reasonably call their attention to the absence of any reason for a change; if there is such a reason, he should remember that, though the bills unpaid at the end of the year have to come in as an addition to the cash receipts, the corresponding amount at the commencement of the year should be deducted. (2) The only claim is for the amount of the net cost of replacement—that is, £75; "depreciation" has to be claimed year by year, and cannot be allowed in a lump sum when the car in question is sold.

LETTERS, NOTES, ETC.

Koplik and Koplik's Spots

An article by Dr. W. R. Bett in the current issue of the *British Journal of Children's Diseases* (April-June, 1931), entitled "Some paediatric eponyms.—III. Koplik's spots," briefly tells the story of the man and his discovery. Extracts are reproduced from Koplik's original descriptions of his spots in the *Archives of Pediatrics*, 1896, the *Medical Record*, 1898, and the *Medical News*, 1899. In the third and final article the author expresses surprise at the slowness with which "this valuable diagnostic sign has made its way," especially in his own country. It was only in 1899 that the *Medical News* described Koplik's spots as "an integral part of the classical symptomatology of measles in the sense that it must enter into the body of medical teaching on that disease." It is true that the literature before Koplik contains descriptions of an exanthem on the buccal mucous membrane, but none of these compare with Koplik's account in accuracy and in tone of conviction. Henry Koplik was born in New York in 1859. After taking his medical degree in 1881 he studied in Berlin, Vienna, and Prague. In 1887 he was appointed attending physician to the Good Samaritan Dispensary, where, two years later, he established the first sterilized milk depot for infants in America. For twenty-five years he was attending paediatrician to the Mount Sinai Hospital. Koplik was a big, bluff, good-natured man, with a white vandyke beard. His sparkling wit and inexhaustible fund of stories made him a pleasant companion. He was essentially a man of the world, who knew how to be kindly and how to be dignified. He died of heart failure in 1927, aged 69. The article is illustrated by an autographed portrait of Koplik and a reproduction in black-and-white of his own coloured drawing of his spots.

Precipitate Labour: Death from Shock

Dr. CHARLES J. HILL AITKEN (Kilnhurst) writes: With reference to the recent article by Professor Miles Phillips (*Journal*, May 16th, p. 833), I should like to record my experience of a case. A young primipara, while standing at the foot of her bed, delivered herself of an eight months living child, the birth lasting fifteen minutes. A "queer feeling" had come on suddenly a few minutes after she had risen from bed after a good night's rest. As foetus and placenta passed from the maternal passages the mother collapsed on to the floor and died. I was called soon after this. The loss of blood had not been excessive, and the uterus was palpable through the abdominal wall. Post-mortem examination revealed fluid in the left side of the chest, extensive old-standing pleural adhesions on the right side, and a pericardium adherent to the heart. The kidneys were healthy, and no obvious tuberculosis was found in the lungs. Inquiry showed that the deceased had refused the medical examination suggested by the midwife engaged to attend, and that her friends had, for some time, thought that she looked tired and ill. Death was due to the sudden emptying of the uterus, causing shock, which had proved too much for the diseased lungs and heart. Possibly death might not have occurred had the mother gone to bed when she felt "queer." I am indebted to Dr. J. C. Halliman for the post-mortem findings.

Aseptic Vaginal Examination

Dr. C. CHARLESON, F.R.C.S.Ed. (Royal Infirmary, Perth), writes: Since the publication of my notes on aseptic vaginal examination in the *Journal* of July 11th (p. 63), my attention has been called to a similar device by Dr. F. H. Whyte, marketed by Messrs. Mayer and Phelps. Had I been aware of the previous existence of a similar technique I would not, of course, have submitted for publication my notes on that subject.

Grain Poisoning

Dr. J. KELVIN (Rutherglen, near Glasgow) writes to record the following case occurring in general practice: In January of this year a grain labourer, aged 46, began to feel a numbness, with lack of grip, in the hands. I first saw him in April. I found no organic disease anywhere, and I labelled him as suffering from a functional neurosis of the arms. A nerve specialist concurred in this view. A few weeks later the patient complained of lumbar pains and cramps in the legs. In May I found: (1) spasticity, increased reflexes, and inco-ordination in the arms; (2) ataxia; (3) spasticity, knee-clonus, ankle-clonus, and Babinski's sign in the legs. In June I connected his occupation with his illness. Clearly it was a case of ataxic paraplegia, which is due to grain poisoning. Ergotism causes an ataxic paraplegia. Lathyrism is essentially a paraplegia. The special points are: (1) sudden onset; (2) widespread, rapid course downhill; (3) exposure to grain disease—nineteen years in the grain atmosphere, grain and its dust and its insects always "bathing" and "choking" him. More attention should be directed by medical research workers to the question of diseases caused by grain poisoning. Cereals are cultivated haphazardly in soil that is "enriched" by dangerous fertilizers—soil infected by deadly sporing fungi that are parasitic instead of saprophytic. Recall what disastrous effects fungus diseases can have, as in tinea capitis and in actinomycosis.

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 35, 36, 37, 38, 39, 42, and 43 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 40 and 41.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 87.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

76 The Differential Diagnosis of Tuberculous Meningitis

E. SCHIÖDT (*Ugeskrift for Laeger*, May 14th, 1931, p. 526) has made a study of 181 cases of tuberculous meningitis observed at the Blegdam's Hospital in Copenhagen since 1919. The fact that in this twelve-year period so many cases of tuberculous meningitis were admitted to a hospital which would not have received them had the correct diagnosis been made before admission, indicates how difficult the diagnosis of this disease is. Most of the 181 patients were, indeed, admitted with a diagnosis of meningitis, but the character of this meningitis was not specified on admission. Among the many factors discussed by the author in the differential diagnosis is the season of the year. While the incidence of tuberculous meningitis is highest in March, April, and May, acute anterior poliomyelitis is practically confined to August, September, and October, while encephalitis has a definite maximum in February. The chances in an obscure case of a patient suffering from tuberculous meningitis or poliomyelitis will depend, to a considerable extent, on whether the month concerned is April or September. In addition to the 181 cases of tuberculous meningitis studied, there were 126 of epidemic encephalitis, 97 of acute anterior poliomyelitis, 25 of secondary serous meningitis, and 51 of primary serous meningitis. It was found that, in distinguishing between these diseases, a history of tuberculosis in the patient's family, Pirquet's test, and the mode of onset of the disease were of no value. But a personal history of tuberculosis was so common among the adults suffering from tuberculous meningitis, and so rare among the patients suffering from the other forms of meningitis, that this point was of value in the differential diagnosis, though only with adults, and not with children.

77 The Significance of Hypotension

V. PACHON and R. FABRE (*Journ. de Méd. de Bordeaux*, May 30th, 1931, p. 493) find that confusion still exists regarding hypotension and hypertension; to classify these conditions accurately one must differentiate between the condition of the arteries and of the heart. Formerly sphygmomanometry was used for maximal pressures only, and, by accepting this basis, it was considered possible to classify functional vascular conditions as arterial hypertension or hypotension. The minimum pressure, however, is the true basis, because the maximal pressure represents only a brief stage in arterial pressure, and pressure varies greatly in the same person under different conditions, while alterations in the maximal and minimal pressures are not necessarily relative. In the case of a cardio-renal patient suffering from heart failure, although the maximal pressure falls owing to the cardiac failure, the minimal pressure remains high or may even rise. The maximal pressure, taken by itself, may appear normal in such a case, while the minimal pressure remains at about 110 mm., and may conceal the actual hypertension which is indicated by the minimal pressure representing the actual permanent arterial charge, and affording a datum below which the internal arterial pressure does not fall. It is, therefore, the constant arterial charge on which is superimposed the intermittent supercharge due to the ventricular systole, of which the maximal pressure is but the peak. The minimal pressure represents also the total peripheral resistances that the heart must overcome at the commencement of ventricular systole, and controls the initial cardiac effort at the moment of ventricular evacuation, since the minimal pressure closes the aortic valves during diastole. Obviously a high minimal pressure necessitates an increased cardiac effort to ensure ventricular evacuation. High maximal pressures, moreover, are not necessarily pathological; they may indicate vigorous systoles of a strong or slightly overworked heart—a defensive and compensatory reaction in cases of definite hypotension, as, for example, in aortic incompetence. Thus, while a moderate or high maximal pressure may be unimportant, high minimal pressure always indicates hypertension and abnormal resistance that must be overcome by abnormal cardiac effort.

78 Focal Infection and Rheumatic Ailments

R. GORDING and H. BJÖRN-HANSEN (*Nordisk Medicinsk Tidskrift*, May 29th, 1931, p. 337) record a study of 62 cases of rheumatism in which a search was made for focal infections with leucocyte counts. The average duration of the disease before the first examination was six months, and the average duration of the subsequent observation period was two years and nine months. In the first group, consisting of 52 patients (15 men and 37 women), with an average age of 31 years, there were two subgroups. In the first subgroup of 19 patients the leucocyte count was abnormal (more than 7,000 leucocytes, and a displacement to the left of the neutrophil leucocytes exceeding 10 per cent.). With the eradication of septic foci such as infected tonsils and teeth, not only did the blood picture become normal, but all the symptoms disappeared in all these 19 cases. In the second subgroup of 33 patients the articular manifestations dominated the clinical picture, and most of the patients were unfit for work. After treatment, consisting of the elimination of septic foci, 26 of these 33 patients were rendered symptom-free and 2 became much better. The leucocyte count was abnormal in 31 of these 33 cases before treatment; after it, 24 of the 31 abnormal blood counts became normal. In this first group of 52 patients there were as many as 34 in whom the focal infection was traced to the tonsils. The second group consisted of 12 patients (4 men and 8 women), with an average age of 39 years, whose disease presumably began with an attack of acute articular rheumatism. Seven of these patients had developed acute articular rheumatism as a sequel to a sore throat, and all seven were relieved of their symptoms by the elimination of the tonsils. One other patient in this group was also cured by the removal of a septic focus. Of the total of 64 patients, 53 were rendered symptom-free and 2 much improved, but since relapses followed in 6 cases, successes could be claimed only in 49, or about 77 per cent. of the total.

Surgery

79 Traumatic Arterial Spasm

S. NOWICKI (*Lyon Chirurgical*, May–June, 1931, p. 317) describes traumatic arterial spasm as a temporary pathological condition which persists usually for several hours, but seldom for more than two to five days. The artery contracts for a variable distance, dilates, and then recovers its normal calibre. Shortly afterwards the pulse reappears in the peripheral branches of the contracted artery, and the circulation becomes normal. These phenomena usually occur in the large arteries of the limbs, and only once have they been observed in the carotid artery. A case of an agricultural labourer is reported, in which the arterial spasm followed the falling of a tree on his right arm; this caused marked sensory and motor disturbances in the limb. Signs of spasm of the brachial artery were present when the patient was admitted to hospital four days after the accident. In the lower part of the arm and in the forearm the pulse could not be felt; the upper arm was swollen and livid, but uniformly warm, and the patient was in considerable pain. Treatment was continued for nine days, since the patient refused operation,

but the oedema and cyanosis increased, and the right hand became completely cold. On the twelfth day an operation was performed, and it was found on exposing the vascular nervous bundle in the upper arm that there was no apparent injury; the sheath of the vessels was intact, but it was observed that the pulse in the brachial artery ceased below the axilla. After incision of the sheath it was seen that the artery was contracted for about 1 cm.; the walls of the artery appeared normal, although the tension was greater in the contracted portion than above it, where the pulse was stronger than normal. Below the constriction the artery was flattened, depressed, and immobile, and no thrombosis was found. The operation did not improve the circulation; symptoms of gangrene appeared three days afterwards in the skin of the forearm, and a subcutaneous haematoma began to suppurate under the scar. The gangrene spread, while in the wrist and elbow necrosis developed, followed by ankylosis of these joints. A further operation, one and a half years after the accident, showed that the obliteration of the artery still persisted, and that the spasm was complete and permanent. Periarterial sympathectomy did not improve the condition, and the arm was subsequently amputated.

80 Tumours of Joints

P. RAZEMON and G. BIZARD (*Rev. de Chir.*, April, 1931, p. 229) discuss the various types of tumours of the joints and review 74 cases; of these, 45 were benign tumours and 29 malignant. The tumour occurred 63 times in the knee, 8 times in the foot or heel, once in the elbow, and in two cases the site is not defined. Benign tumours comprise lipomas, fibromas, angiomas, and giant-cell tumours of the synovial membrane. Lipomas are usually of inflammatory or traumatic origin and, like the fibromas, are comparatively rare. Angiomas are more common, and have a characteristic appearance which makes the diagnosis easy. The varicosities can be seen under the skin, and coincide frequently with an intra-articular angioma. At the time of operation the tumour is usually visible under the distended capsule, and is often about the size of a hazel nut, bluish and elastic, with prolongations towards the head of the fibula and the middle line. On opening the capsule, more or less abundant blood-stained fluid may be drained off. Giant-cell tumours of the synovial membrane are of two different types—stalked and diffuse. Trauma is most frequently the etiological factor in the production of these tumours. Malignant tumours are usually found to be one of the various types of sarcoma or synovial endothelioma, are less common than benign tumours, and range in size from that of a prune to 7 by 5 cm. A case is reported in which the knee of the patient measured 87 cm. in circumference. These tumours have an arborescent appearance, and as a rule the tumour is not encapsuled. Diagnosis of malignancy is frequently impossible without a histological examination. Treatment of the various types of joint tumours depends upon the diagnosis; when this is uncertain, an arthrotomy is the operation of choice. In cases of benign tumours the prognosis is good; for tumours with a pedicle complete removal gives good results; for the diffuse type, synovectomy is recommended. When a definite diagnosis of malignancy has been made, amputation is the only safe procedure; when the diagnosis is doubtful, the tumour should be removed for histological examination, and, if found to be malignant, amputation must be performed immediately.

81 Tuberculous Hydrocele

P. CARTIER (*Bull. de l'Acad. de Méd.*, June 30th, 1931, p. 1034) discusses the etiology of the so-called essential hydroceles, and reports conclusions reached by investigating a series of 86 fluids from 81 patients, 5 having a double hydrocele. In 2 cases gonococci were isolated; in 6 a diplococcus, which has been previously described; in 2 unknown bacilli; and in 24 (27.9 per cent.) tubercle bacilli of slight virulence. It is suggested that the finding of the last-named bacilli proves that there exist in man very benign, easily curable types of surgical tuberculosis, and that these are more frequent than is thought. Many hydroceles of obscure etiology, and many serous effusions, may be due to non-bacillary forms of tuberculosis. In further support of the work, BRINDEAU, P. CARTIER, and POUGIN (ibid., p. 1036) argue that some tuberculous hydroceles are congenital, and cite two cases in confirmation of this view. This form of tuberculous infection in infants, transplacental in origin, has not yet been described. The prognosis is always very grave. In the two cases here recorded the patients died; neither had received B.C.G., and in each the hydroceles were non-communicating.

82 Strangulation of Meckel's Diverticulum

G. S. DONATI (*Il Policlinico*, Sez. Chir., June 15th, 1931, p. 278) reviews the pathology of Meckel's diverticulum and reports the case of a man, aged 79, who without any previous history of hernia was admitted to hospital with a history of abdominal pain and swelling in the inguinal region of four days' duration. The bowels were open, and there was no vomiting. The swelling was the size of a nut, painful and irreducible. There was no distension of the abdomen, and the general condition was good. A diagnosis of strangulated epiploön was provisionally made and laparotomy performed; it was then found that the diverticulum was implanted on a loop of the small intestine. That this was a true and not a false diverticulum was established by its size, and by the presence of serous, longitudinal, and circular muscular fibres. The diverticulum was excised and the intestine closed. The patient made a good recovery.

Therapeutics

83 Potassium Permanganate in Pneumococcal Meningitis

M. H. WEINBERG (*Journ. Nerv. and Ment. Dis.*, July, 1931, p. 38) reports a case of pneumococcal meningitis (Type III) which was treated by potassium permanganate enemas with encouraging results. The dosage used was 4 ounces of Nott's standard solution, 2 grains of this salt in 1½ pints of water. (See *British Medical Journal*, 1925, i, 443, and 1926, ii, 109.) The potassium permanganate is dissolved in cold water in an earthenware or glass dish, and hot water is added to make the solution comfortably warm; it is introduced slowly into the rectum after a cleansing enema has been administered. The patient lies on his left side, and remains thus for about twenty minutes in order to ensure retention. In Weinberg's case the patient was almost moribund, but repetition of the enema at four-hourly intervals resulted in an uneventful recovery, the temperature returning to normal eleven days after the treatment was begun. The author suggests that the manganese ion acts as a detoxicant mainly, facilitating the progress of natural auto-immunization. The infecting organisms disappear rapidly from the cerebro-spinal fluid. Weinberg urges the further trial of this method, which obviates the necessity for such severe measures as frequent lumbar and cisternal punctures, ventricular lavage, and the injection of powerful and irritating drugs into the subarachnoid space.

84 Intravenous Injections of Liver Extract

Since Cohn prepared liver fractions which gave no specific reactions and did not reduce blood pressure, it has been possible to administer the active liver principle intravenously. W. B. CASTLE and F. H. L. TAYLOR (*Journ. Amer. Med. Assoc.*, April 11th, 1931, p. 1198) review the recent work on liver fractionation, and state that a readily prepared extract (fraction G), hitherto administered orally, has been found suitable for intravenous injection, and highly potent in pernicious anaemia. This method hastens the response to treatment. Maximal reticulocyte responses were obtained by a single injection of the amount of extract derived from 100 grams of liver; a repetition of this dose at ten-day intervals has produced a satisfactory upward progression of the erythrocytes. A possible etiological and therapeutic significance of these observations is suggested. The authors allude to the

potential dangers in the intravenous injection of any substance, and emphasize that the therapeutics of this extract are still largely unknown, the present need is not for new sources of the active principle, but for persistence in the use of sufficient quantities of those preparations already available

85 Acetylcholine Bromide in Tuberculosis

From consideration of their physiological effects, M PERRIN and MARCELLE KUNTZ (*Paris Med*, May 23rd 1931, p 494) rank the salts of acetylcholine, the chloride as well as the bromide as antagonists of adrenaline They are vaso-dilators and hypotensors, acting especially on the peripheral arterioles They are eliminated rapidly It is essential to commence with small doses, watching the action on the urine, the heart, and the blood pressure The solution should have been just made at the time of injection muscarine is apt to be formed in old solutions The authors keep the bromide, in powder form, mixed with double the quantity of anhydrous glucose They find it less painful for subcutaneous injection than the chloride Its field of action is wide It acts as a vaso-dilator in spasm of the central artery of the retina Raynaud's disease, intermittent claudication, the gastric crises of tabes and lead colic It has also a hypotensor effect in the hypertension of youth, and is particularly effective in the sweats of tuberculosis as was shown by Villaret and Even in 1928 The authors' routine is to give 0·5 gram of camphoric acid for one or two days for these sweats increasing the dose, if necessary, to 1 gram during the next four or five days If this fails they have recourse to subcutaneous injections of acetylcholine bromide—three doses of 2 cg at three day intervals, each given two hours before the sweat is expected The first or second dose is often sufficient The authors rarely give 4 cg, and have not exceeded this dose Of the 10 cases observed, 3 have shown slight improvement while in 7 the effect has been remarkable, the sweats having disappeared for a week or two There have been no untoward results

86 The Treatment of Anaemia

G R MINOT (*New England Journ Med*, May 21st, 1931, p 1104) finds that many cases of anaemia depend upon inadequate nutrition, either from faulty diets or, indirectly, from some personal inadequacy of the individual Effective treatment of pernicious anaemia implies a sufficiency of potent material, whether liver, kidney, stomach, pancreas or brain, for the given individual throughout life If there is difficulty in absorption the material should be introduced intravenously The objective is the restoration to normal in all respects, both of the blood and of the patient generally Larger doses are required in older than in younger individuals, when cardio-vascular disorders occur, and in the presence of infections, lesions of the nervous system, and other complications Perseverance with maximal amounts is imperative The principles in the treatment of anaemias that can respond to iron are essentially the same as in the case of pernicious anaemia There are patients with simple hypochromic achlorhydric anaemia who must take iron with regularity for the rest of their lives Whole liver and iron should be given in any form of anaemia where there has been chronic loss of blood The 'shot gun' prescription of large amounts of liver and iron offers the greatest chance for the anaemic individual, but such routine treatment leads to neglect of the individual requirements

87 Hydrochloric Acid in Chronic Constipation

H WINTOCH (*Munch med Woch* May 29th, 1931, p 913) remarks that whereas the association of achlorhydria with diarrhoea is well known the fact that in many cases of chronic constipation achlorhydria or sub-acidity is found seems to have escaped the consideration it deserves In a series of cases of constipation those patients in whom the gastric acidity was low were treated by dilute hydrochloric acid (10 drops in water with meals), often with remarkable success Since many of these patients had previously tried numerous other methods of treatment without success, the author thinks the effect of the acid cannot be explained on purely psychological grounds and claims that the method is at least worthy of an extended trial

Anaesthetics

88 Apparatus for Simple and Combined Anaesthesia

H FRINKEN (*Schmerz Narkose Inaesthesie*, May, 1931, p 41) describes and illustrates fully the mechanism of an apparatus by which ether oxygen, chloroform oxygen, ether chloroform-oxygen and any form of gas or acetylene anaesthesia can be administered The amount of the gas or anaesthetic being used can be readily ascertained and regulated Anaesthetics can be administered under any desired pressure (as for thoracic operations) by the addition of a simple apparatus to the outlet of the mask The mask itself is of the rubber type similar to that ordinarily employed for nitrous oxide administration, with the usual ventilator allowing for pure air anaesthetic, or "rebreathing If necessary, a definite percentage of carbon dioxide can be supplied with oxygen alone, or with the anaesthetic being used Special precautions have been taken to avoid all possibility of explosion

89 Spinal Anaesthesia

C R STEINKE and H V SHARP (*Med Journ and Record*, April 15th, 1931, p 374) record their experience of spinal anaesthesia in 106 cases (53 males and 53 females) the youngest patient was 16 and the oldest 72 In 95 of the cases 2 to 3 c cm of spinocaine was injected, in five, 2 grains of apothesine, and in six, 150 to 200 mg of neocaine The operating time averaged 41 minutes and good anaesthesia was obtained in 85 of the cases, fair in 18, with failure in 3, in 23 instances supplementary ether, nitrous oxide and oxygen, or local anaesthesia was required In 47 cases the operations were abdominal, in 17 of the lower extremity, and in 42 anal or perineal A restful previous night was assured by some barbituric acid sedative, and half an hour before the operation 1/4 grain of morphine was administered hypodermically with 1/200 grain of scopolamine or 1/150 grain of atropine In 56 cases spinal anaesthesia was used because of some contraindication to inhalation anaesthesia, and the complications were less than might have been expected from other methods in that shock was minimized, and the necessity for catheterization lessened In many cases fluids could be given before, during, and after the operation, and the diet be more rapidly varied and increased There was less risk of bowel distension, normal motions being obtained earlier convalescence was shortened

90 Anaesthesia Induction in Diabetics

I I LEMANN (*Anesthesia and Analgesia*, May June 1931, p 142) believes that starvation, vomiting, and acidosis are the most menacing dangers incurred by diabetic patients in surgical operations Pointing out the risks of hyperglycaemia and acidosis produced by chloroform and ether, he states that the anaesthetics of choice for these cases are nitrous oxide and ethylene Notes on the blood sugar and plasma CO determinations are given in a series of 17 diabetics, 14 were given ethylene 2 ether, and one nitrous oxide There was in no instance any post operative plasma CO_2 value even approaching that of an acidosis These good results are attributed to the pre operative preparation, and the use of insulin and abundant carbohydrate during and after the operation An extra supply of carbohydrate and an increased insulin dose were given about six to eight hours before the operation During the course of the anaesthetic administration 20 c cm of 50 per cent glucose was injected intravenously, with 1 to 2 units of insulin per gram of glucose The danger of adding hypoglycaemia to shock must be avoided both conditions are similar If the blood pressure falls during the course of anaesthetization of a diabetic patient, glucose should be administered intravenously and epinephrine hypodermically, both substances raise the blood sugar level

Obstetrics and Gynaecology

91 Trial Labour

R. KELLER (*Bull. Soc. d'Obstét. et de Gynécol. de Paris*, April, 1931, p. 304) describes the trial labour which he employs in moderate degrees of pelvic contraction. In the first stage an endeavour is made to correct exaggerated uterine anteversion or lateral flexion. If cervical dilatation is slow, functional rigidity is treated by the exhibition of antispasmodics, and anatomical rigidity by multiple incisions. Artificial rupture of the membranes should not be performed until a dilatation of 5 cm. has been secured. Anomalies of flexion of the foetal head call for rectification, if possible. In Keller's practice the duration of the trial is extended in certain cases, in the absence of pyrexia, to twenty-four hours. In a patient who has had one Caesarean section a second pregnancy does not contraindicate, but rather demands, a second test labour at term; in a large proportion of these cases spontaneous delivery follows, although in very rare instances a rupture of the uterus has occurred during the trial. The corrected mortality in Keller's last series of a hundred trial labour cases has been 2, and the gross morbidity 37.

92 Herpes of the Urinary Bladder

A. GREMME (*Zentralbl. f. Gynäk.*, May 2nd, 1931, p. 1558) describes a case of herpes simplex of the bladder in a woman, aged 31, who was admitted to hospital for right-sided *B. coli* pyelitis. Cystoscopy was performed on admission and revealed redness and swelling of the right ureteral orifice, the rest of the mucous membrane being normal. Two days later typical herpes labialis developed, and a cystoscopy on the next day showed about twenty small shiny vesicles on the right side of the bladder. The vesicles on the lips went through the usual stages of turbidity of contents, drying, and scabbing; those in the bladder, observed by a series of cystoscopic examinations, passed through the same changes and were nearly healed about ten days after their first appearance. Although three definite cases of herpes zoster of the bladder have been recorded, and nodular and vesicular eruptions of the mucous membrane (cystitis, cystica, or nodularis) have sometimes been described as herpes, Gremme cannot find another undoubted case of herpes simplex of the bladder in the literature. As the patient was suffering from pyelitis, it is unfortunately not possible to say whether the disease is associated with symptoms.

93 Painful Breasts

M. CUTLER (*Journ. Amer. Med. Assoc.*, April 11th, 1931, p. 1201) believes that the pathogenesis of painful breasts consists in desquamation of the epithelial cells in the ducts and acini, with hyperplasia of the peri-canicular and peri-acinous connective tissue. The corpora lutea of menstruation and pregnancy are responsible for the normal physiological hypertrophy of the mammae; clinical and other forms of evidence indicate that the excessive hyperplasia giving rise to diffuse pain and nodularity in the breasts may be due to excessive stimulation of the corpus luteum. This overactive body also suppresses ovulation, and exerts an oestrus-inhibiting action. Administration of the dried and powdered residue from the fresh ovaries of hogs or cows, after removal of the corpus luteum, apparently causes a cessation of abnormal epithelial and connective tissue hyperplasia by counteracting excessive corpus luteum secretion, thereby diminishing or removing its overstimulating effect on the mammary elements. The oral administration of this substance in many cases of painful breasts has relieved pain and tenderness, and brought about a definite softening of the breasts, the actual disappearance of painful nodules, a more normal state of menstruation, and an improvement in the general condition of the patients. A note is appended as to the specificity and effects of ovarian residue and other internal secretions.

Pathology

94 Defects of Conduction in the Alimentary Canal

As a result of researches on animals and the human subject, E. F. MÜLLER and W. RIEDER (*Münch. med. Woch.*, June 19th, 1931, p. 1033) state that the active phase of peristaltic movement is that of relaxation, and that the contraction which follows is a secondary effect. The normal state of the muscle is one of contraction, so that the sphincters ordinarily remain closed, and are only opened by the appropriate stimulus from above. This stimulus fails, so far as the cardiac sphincter is concerned, when the vagal fibres are cut in animals, or in human cases of so-called cardiospasm. The sphincter is found to be in a normal resting state, and not in a condition of true spasm. Spasm is only excited by mechanical obstruction, or by the presence of foreign bodies (including ulcers). Spasm is characterized by pain, ischaemia, and a palpably hard condition of the muscle; it occurs always above the obstruction or other lesion. Failure of relaxation, on the other hand, is accompanied only by the symptoms of the coexisting deficiency of conduction, and occurs below the site of the lesion, if one can be determined. The delayed emptying of the stomach which sometimes occurs after gastrectomy is an example of this condition; it is due to section of the nervous paths. Finally, dilatation is generally due to inflammatory conditions in the neighbourhood of the intestines, especially if the serous coat is involved.

95 Cultivation of Tubercle Bacilli from the Blood

A. MUGGIA (*Soc. Internaz. di Microbiologia, Boll. Sez. Italiana*, May, 1931, p. 181) has attempted to confirm Loewenstein's work on the presence of tubercle bacilli in the blood stream of patients suffering from various types of tuberculosis. By using a special technique Loewenstein reported that he had cultivated tubercle bacilli from the blood of 54 out of 140 cases of pulmonary tuberculosis, from 18 out of 28 laryngeal cases, from 13 out of 22 renal cases, from 23 out of 51 skin cases, and from one out of 21 cases of acute articular rheumatism. Using Loewenstein's technique, the author has studied four cases of pulmonary tuberculosis with positive sputum and five cases of acute articular rheumatism. The results were negative. E. FAVERO (ibid., p. 188) has similarly attempted to repeat Loewenstein's work. Besides using this author's technique, he treated the blood by a method of his own, included Petragnani's medium, and inoculated each specimen of blood into a young guinea-pig. Forty specimens of blood were examined from patients with pulmonary tuberculosis with negative sputum, 320 cultures being put up. Incubation was continued for 60 days. The results were completely negative; not a single positive culture was obtained from the blood, nor did any of the guinea-pigs develop tuberculosis.

96 Active Immunization against Poliomyelitis

Success in actively immunizing monkeys against poliomyelitis has been attained only with living virus; the danger of infection during treatment is, however, constantly present. Rhoads attempted active immunization with a combination of immune serum and virus. M. BRODIE and A. GOLDBLOOM (*Journ. Exper. Med.*, June 1st, 1931, p. 885), experimenting with this method found that a combination of poliomyelitic virus and specific human serum was effective in conferring active immunity. For each gram of virus given intradermally 6 c.cm. of serum, injected subcutaneously, was requisite to protect a monkey from paralysis, and some degree of active immunity was induced. Immunity without symptoms was secured when the serum was given at the time of, or within three days preceding or following inoculation of the virus. In producing immunity, virus preceded by serum administration is probably less effective than when it is given simultaneously with or before the serum. The virus neutralization test is more sensitive than the direct intracerebral test for determining the development of immunity.

If it bear any of the Trade-Mark names:

Evans'

PURGOIDS

Purgoids present a most effective combination of Phenolphthalein, Aloin, Ipecacuanha, Belladonna, etc., in sugar-coated tablet form. They are of great value in cases of constipation, peristalsis being promoted without griping, and intestinal secretion increased.

In addition to their use in constipation of long standing, Purgoids are to be commended as a general aperient in temporary conditions and after operations.

FUNCTIONAL NERVOUS DISORDERS.
CALDECOTE HALL, NUNEATON.
RESIDENTIAL TREATMENT of the most modern kind is carried out under the personal direction of the Resident Medical Superintendent in this beautiful Country Mansion. Fees are moderate. *Full particulars from the Resident Medical Superintendent:* A. E. CARVER, M.D., D.P.M. Telephone: Nuneaton 241.

STRETTON HOUSE,
Church Stretton, Shropshire.
A PRIVATE HOME for the treatment of Ladies suffering from Mental or Nervous Illness including the allied disorders of early Mental and Nervous cases are received. Alcohol and the Drug Habit. All types of mild Certified cases as Voluntary Patients under the provisions of the Mental Treatment Act, 1930. Brochure Hill country. See *Medical Directory*, p. 2138.—Apply to Medical Superintendent, Tel. 10 P.O., Church Stretton.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON.
FOR THE UPPER AND MIDDLE CLASSES ONLY.
President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.
Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or who wish to prevent recurrent attacks of mental trouble; temporary patients; and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.
This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombieres treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.
Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL.
The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

HAYDOCK LODGE,
NEWTON-LE-WILLOWS, LANCASHIRE.
'Phone: 11 Ashton in Makerfield.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES either voluntarily or under Certificate. Patients are classified in separate buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self supported by its own farm and gardens, in which patients are encouraged to occupy themselves. Every facility for indoor and outdoor recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT.

COURT HALL, KENTON, EXETER,
SOUTH DEVON.
For the care and treatment of Ladies suffering from Mental Diseases. Limited to eight patients. Telephone: Starcross 19.

CLIFFDEN, TEIGNMOUTH, in connection with Court Hall, for early and convalescent cases. Cliffden is a large well appointed house, with lovely views of the South Devon Coast. It is beautifully situated in grounds of 19 acres. The gardens are very attractive, and there is a private road to the beach.

Resident Physicians: BERTHA M. MULES, M.D., B.S.; ANNIE S. MULES, M.R.C.S., L.R.C.P. *Telephone*: Teignmouth 289.

TYKEFORD ABBEY, NEWPORT PAGNELL,
BUCKS.
FUNCTIONAL NERVOUS DISORDERS, MEDICAL & CONVALESCENT CASES.
An approved Nursing Home for reception of Female Cases under the Mental Treatment Act.

The Home is a Mansion of Historical interest, standing in 9 acres of garden and grounds, and is situated 14 miles from Northampton, and 12 miles from Bedford on the main London to Northampton Road, fifty miles from London. Both sexes are accommodated. Psycho-Therapeutic Treatment is used extensively in suitable cases. Radiant Heat, X-Ray, and Ultra-violet Light. Diathermy and Foam Baths. Billiards, tennis, etc. Fees from five gns. per week. Apply, Dr. D. E. M. DOUGLAS MORRIS. *Telephone*: Newport, Pagnell 121.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.
This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance [illegible] and from its singularly healthy position and comfortable every facility for the relief and cure of those mentally and Temporary Patients received.

THE RESIDENTIAL TREATMENT OF ALCOHOLISM & DRUG ADDICTION

RENDLESHAM HALL

(Postal Address)—**WOODBRIDGE, SUFFOLK.**

Rendlesham Hall, which is open to receive patients, is essentially a Sanatorium. Its daily life and routine are that of an ordinary comfortable holiday or health resort, or of a large country house. Each patient has all the privileges of a guest consistent with the prescribed medical treatment.

Rendlesham Hall has 45 bedrooms, and about 450 acres of gardens and park. It has also a private nine-hole golf course, tennis and croquet lawns, and bowling green.

Illustrated booklet, giving particulars as to terms, etc., can be had on application to the

RESIDENT MEDICAL SUPERINTENDENT.

Telegrams and Telephone: Wickham Market 16.
(Toll Call from London.)

CHANNEL VIEW SANATORIUM

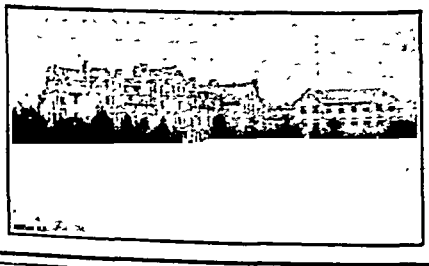
"CHANNEL VIEW" SANATORIUM.

The Council of the Southern Convalescent Homes, Incorporated (without profits), are able to offer T.B. sufferers the advantages of reduced charges at their Sanatorium.

The Sanatorium is practically on the sea bank at Lancing, Sussex, one thousand feet of which, with the intervening meadow, are the properties of the Corporation.

Lancing ho'ds a record for sunshine. The air of the neighbourhood is of the purest, while the absence of seaweed is also a valuable asset.

A report by the Medical Officer for the District, speaking of Lancing, said:—"There is every prospect that the growth of the district will continue, especially as it is recognised that Lancing possesses, among other natural advantages, one of the finest stretches of sand on the South Coast."



The Staff (Matron and Nurses) are fully trained and State registered. The charge is 35/- per week, which includes Medical Officer, etc. Also full board, best viands. Ladies are given the South block. Strawson revolving huts are included in the equipment. The gardens cover two acres, and provide both fruit and vegetables. Inspection invited.

Write for free booklet giving full details to

SECRETARY, HOMES' OFFICE, LANCING-ON-SEA, SUSSEX.

BRITISH SPAS
ARE BEST

and membership of the British Spas Federation is a guarantee of efficiency

AT British Spas, treatment is only given (except in a few minor cases) upon medical prescription.

At British Spas the staffs are educated and properly trained and, in some cases, medically trained and medically certificated.

Equipment and administration are thoroughly up to date and scientific. Every new treatment is tested and reported upon before being adopted.

British Spas are also remarkably fortunate as regards situation, scenic beauty and pure air. These factors, combined with the social amenities of a home town, aid the cure considerably.

BATH Hot Springs (120° F.) Radio-active. Royal Baths extensions now open.

BRIDGE OF ALLAN Saline Water. Rich Calcium Bromide and Iodine Content.

BUXTON Radio-active Mineral Water. New Natural Baths. 3 Guineas Course.

LONDON HOSPITAL MEDICAL COLLEGE & DENTAL SCHOOL.

THE WINTER SESSION will Open on Thursday, October 1st.

The Hospital is the largest in England. There are 839 beds in constant use. Last year: number of in-patients, 14,256; out patients, 86,554; attendances, 529,545; dental patients, 6,063; major operations, 7,401.

The MEDICAL COLLEGE and DENTAL SCHOOL are essentially modern, with large laboratories equipped with the latest and the most approved appliances. The STAFF is so large as to permit of individual attention being paid to all Students.

MEDICAL UNIT.—A Clinical Unit in Medicine, under the charge of a whole time Director, provides for the more elaborate methods of diagnosis and treatment, and takes a leading part in the initiation and co-ordination of medical research.

RESEARCH FUNDS of approximately £113,000 give unrivalled facilities for Medical Research.

SCHOLARSHIPS and PRIZES to the value of £1,158 are awarded annually, including four Open Entrance Scholarships to the value of £350 and two Entrance Scholarships open to students of the Universities of Oxford and Cambridge to the value of £200.

APPOINTMENTS.—Over 160 Appointments are made annually from Students of the College recently qualified.

SPECIAL COURSES are held for all the University Examinations, for the Primary and Final Fellowship Examination of the Royal College of Surgeons, and for the Membership Examination of the Royal College of Physicians.

HOSPITAL PRACTICE.—Exceptional opportunities are offered to qualified Practitioners wishing to attend the General Practice or the Practice of a Special Department of the Hospital.

A Clubs' Union, an *Athletic Ground* of over 13 acres, and a *Students' Hostel* promote the recreation, health, and comfort of the Students.

For Prospectus and Particulars apply to the Dean (Professor WILLIAM WRIGHT, M.B., D.Sc., F.R.C.S.), who will be pleased to make arrangements for anyone wishing to see the Medical College and Dental School.

MILE END, E.1.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL MEDICAL SCHOOL.

(FOUNDED 1816.)

Telephone: TEMPLE BAR 1457. BROAD STREET, HOLBORN, W.C.2. (Near British Museum Station)

The Hospital has just been rebuilt and has 86 beds, including fourteen private rooms for paying patients. The new building has been specially designed for clinical teaching and post-graduate study.

Classes for the D.O.M.S. Examination Part I and II commence in October.

Out patients are seen daily at 1.30 o'clock. Operations are performed at 3 p.m.

The Pathological and Bacteriological departments will be pleased to report on specimens sent in by Ophthalmic Surgeons or Hospitals.

Qualified medical practitioners and registered students may join at any time. For particulars apply to the Dean or Secretary at the Hospital.

Post-Graduate Teaching, West London Hospital.

Continuous Clinical Instruction daily from 10 a.m. to 4 p.m.—Post-Graduates may enrol at any time for any period from 1 week to 3 months.—Special facilities for "Study Leave," and for those wishing to take a course under the "Grant-aided Scheme for Post-Graduate Study by Insurance Practitioners."—Anaesthetic Courses.—Clinical Assistantships.—Annual Membership Tickets at Special Terms available for General Practitioners who wish to attend the Hospital Practice at irregular intervals.

Prospectus from the DEAN, West London Hospital, Hammersmith, W.6.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)

(FOUNDED 1880.)

12, Stratford Place,

Oxford Street, W.1.

Tele Address: Triform, Wesdo—London.

Telephone: Mayfair {1783 1788

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION have every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUM TENENS.

Assistants and Locum Tenens can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Accounts, etc.

An Invitation to the Medical Profession

Cow & Gate Factories in Somerset & Dorset

We extend a hearty invitation to any members of the Medical Profession who may be motoring in the neighbourhood of our Somerset and Dorset Factories, to see for themselves the scrupulous care and expert scientific control which is exercised at every stage in the preparation of our Milk Foods.

Last year we dealt with over 7,000,000 gallons of milk, and over 1,000,000 tests were made at various stages of the process which is carried out by special COW & GATE Improved Roller Machines giving almost complete sterility with full vitamin and mineral conservation

We shall also be glad to send you an invitation card or to arrange for special visits of members of any recognised Medical Society or Association on receipt of the enquiry form below

Cow & Gate Milkfood

I should like { an invitation card / particulars as to arrangements for a party } to visit your factory.

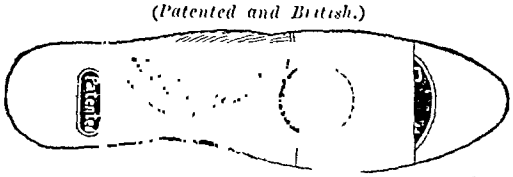
In large variety from £10 10 0 complete.

All lenses mounted, and adjustable trial frame.

Secondhand cases frequently in stock at tempting prices.



"FLAT FOOT"

or a "Falling of the Arch"

Is the cause of many true and false ailments. There are aching, swollen or painful feet, walking is a trouble, one soon gets tired, ankles are weak and liable to "turn over," cramp at times in the toes, feet, or legs, weakness at the knees; there are pains similar to rheumatism or sciatica—all traceable to the condition of the feet.

THE "PNEUMETTE" IS THE REMEDY.

(Patented and British.)

THE ONLY FOOT ARCH SUPPORT WITH AN AIR CUSHION.

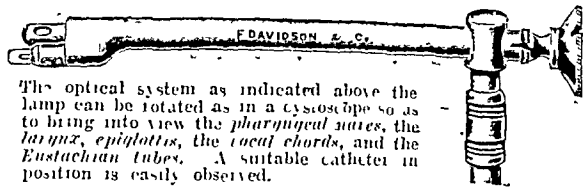
YOU WALK ON AIR—not on metal. You don't feel them—only the wonderful support they give.

The Effect in most cases is Immediate.

What the Pneumatic Tyre is to the car **"Pneumettes"** are to the feet.

MODEL A.—For Flat Foot or Trouble under Instep. *Price per pair 16s. 6d.*

MODEL B.—Combined Support for Main and Metatarsal Arches. Price per pair, 17s. 6d.



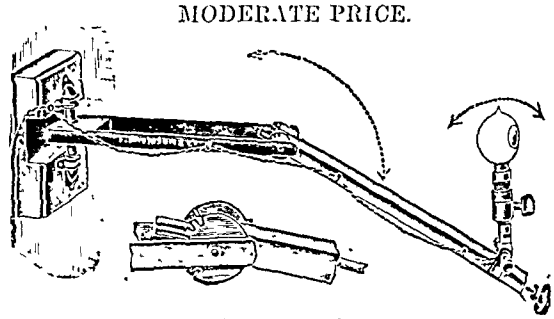
PAMPHLET ON FOOT TROUBLES, with an Article, "The Medical Aspects of Flat Foot," by an eminent London Physician, free.

"Pneumettes" may be prescribed for panel patients through their insurance societies.

ELECTRIC PHARYNGOSCOPE

(Foreign)

(New optical system giving much improved view.)



The optical system as indicated above the lamp can be rotated as in a cystoscope so as to bring into view the *pharyngeal mucus*, the *larynx*, *epiglottis*, the *vocal chords*, and the *Eustachian tubes*. A suitable catheter in position is easily observed.

"I have found it invaluable."——, M.D., 17/12/29.

Pharyngoscope, "Davon" Battery, and Rheostat in Walnut Box	7 5 0
Pharyngoscope alone	5 15 0
"Davon" Battery 7/6. Walnut Case	10 0
Pharyngoscope with battery in handle (not the "Davon")	5 15 0
Or complete with Electric Auriscope for diagnosis, operating, aspirating, and massage, in Oak Case	8 15 0

THE "DAVON" BRACKET.

Well made and serviceable at a very MODERATE PRICE.

Price without bulb £2 2 0.

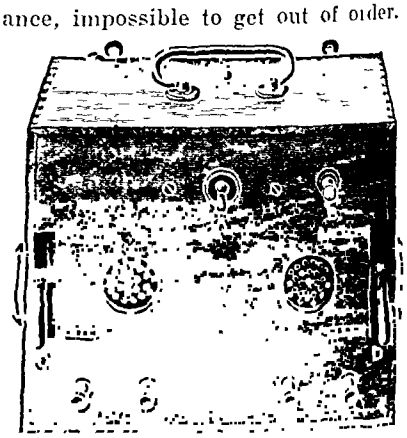
Target frosted bulbs (please state voltage) each 3/6.

Another Achievement.

THE "DAVON" A.C. MAINS SET

for Light and Cautery.

A perfect appliance, impossible to get out of order.



Made on a new principle.

EARTH FREE.

Descriptive leaflet free.

Price £6 10 0.

Please state voltage and periodicity.

WITH SUPPLEMENT

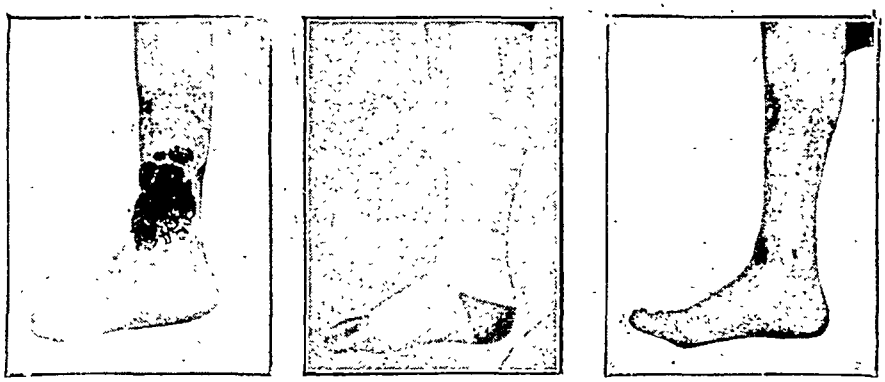
No. 3682 SATURDAY, AUGUST 1, 1931 Price 1/3

The "Allenburys"

"CHARKAOLIN"

GRANULES

"Charkaolin" is a highly efficient agent for the treatment of intestinal infections characterized by abnormal fermentation and the formation of toxins. It combines the absorbent properties of highly activated vegetable charcoal with the well-known toxin adsorbing qualities of "Osmo" Kaolin.



It is in the form of fine, clean granules which disintegrate rapidly in water and diffuse their ingredients evenly throughout the liquid. "Charkaolin" is tasteless, forms a fine suspension in water and is, therefore, quite easy to take.

Descriptive literature and a clinical trial sample will be sent on application.

ALLEN & HANBURYS LTD.

Telephone— Bath Street 3201 (10 lines.) LONDON, E.2. Telegrams— "Greenburys Beth London"

AN INDEX OF

DIFFERENTIAL DIAGNOSIS OF MAIN SYMPTOMS

By Twenty Representative Contributors.

Edited by

HERBERT FRENCH, C.V.O., C.B.E., M.A., M.D.Oxon,, F.R.C.P.

Consulting Physician to Guy's Hospital

This work is of practical utility to medical men whenever difficulty arises in deciding the precise cause of any particular symptom of which a patient may complain It covers the whole ground of Medicine, Surgery, Gynaecology, Ophthalmology, Dermatology, and Neurology.

"Both authors and publishers deserve great praise for producing a volume which in substance brings the highest credit to British medicine, and in format holds its own with the most lavish of transatlantic productions"—BRITISH MEDICAL JOURNAL

"The fund of knowledge contained in this volume is incalculable . admirably illustrated"—LANCET.

"Beyond question a *tour de force* . . . will be found a friend in need at all times"—PRACTITIONER

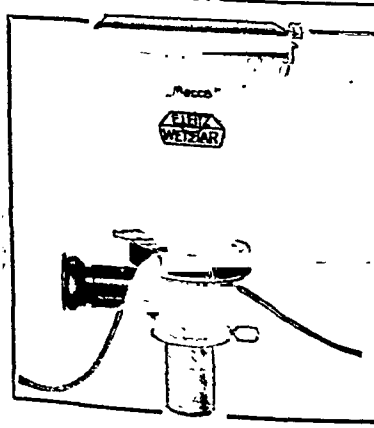
SAMPLES UPON APPLICATION.

WITHOUT OFFENCE The Collection of Overdue Accounts

The reason Medical Accounts are paid last is as follows:—



The average man's income is divided into four channels: RENT, FOOD, CLOTHES, and PLEASURE. No provision is made for ill-health: hence the necessity to persuade most people to pay.

Your visiting card marked "B" placed in an envelope will bring our Prospectus.

All Medical Institutions and Nursing Homes are included in our scope.

A unique service ensuring the more constant use of radiography——

THE METHOD and its results

The apparatus is assembled at the patient's bedside and one small line, carrying both the electric and signal wires, is led from the car through any convenient window. The driver on the car then supplies current as and when required by the radiographer.

Immediately the exposures are made the films are developed on the car, and the finished negatives are ready to be seen within about ten minutes.

A Potter Bucky diaphragm and fluorescent screen are also carried. Great penetration of any part of the body is ensured, and the definition of the negative is rendered equal to that of any permanently installed apparatus.

VERY often it is inadvisable to move a patient for an X-ray examination. More often still the advantages of such an examination cannot be enjoyed because of the difficulties involved. To-day in such cases as these X-ray examinations can equally well be made at the patient's bedside.

A powerful portable apparatus is available day and night for service anywhere—under the control of an experienced radiographer.

Within forty minutes of arriving at a house the negatives are ready for inspection—the films being developed on the car, which is fitted up as a dark room.

The taking of the radiographs can be conducted throughout under the supervision of the medical practitioner concerned.

Seven years' experience in X-ray car service has produced a simplicity of service and a speed of working which constitute a unique service to the medical profession—making possible the more constant use of radiography at surprisingly low prices.

Any medical practitioner is invited to study the results of this method of radiography at any time, on application to the Company.

Full details, in the form of an interesting descriptive booklet, will gladly be sent on request.

Write, wire or telephone to-day——

To Members of
The British Medical Association.

Dear Sirs,

A new protection for the public has been devised by the American Medical Association under governing rules for the approval and acceptance of Food Products.

We feel sure you will be interested to learn that Libby's Evaporated Milk has been submitted to the Committee on Foods of the Council on Pharmacy and Chemistry of the American Medical Association, and we are proud to say, has passed the test successfully, so that we feel more confident than ever in offering it as the best foundation for Infant Feeding.

On the accompanying sheet you will find the report of the Committee on Foods of the Council on Pharmacy and Chemistry of the American Medical Association.

Clinical data will be gladly supplied on request.

Yours truly,
Libby, McNeill & Libby, Ltd.

COMMITTEE ON FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COMMITTEE ON FOODS OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION, AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG, *Secretary.*

LIBBY'S STERILIZED UNSWEETENED EVAPORATED MILK

Manufacturer.—Libby, McNeill and Libby, Chicago.

Description.—An unsweetened evaporated milk.

Manufacture.—The milk is collected under prescribed conditions of sanitation, strained, cooled to 60° F. or under and delivered to the condensary each day. The delivered milk is tested for odor and acidity; a "reductase test" with methylene blue is applied. Speed of destruction of the color is indicative of cleanliness and the previous treatment. Unsatisfactory milk is rejected. A bacterial count is made each week of a composite of samples of all deliveries.

The accepted milk is passed through steam-heated coils into stainless steel or glass-lined tanks. The heated milk is concentrated in "vacuum pans" at a temperature of from 130° to 135° F. The low temperature and absence of air has little destructive action on vitamins A and B (complex). The concentrated milk is homogenized by forcing under high pressure through small apertures, which disperses the fat in fine globules and prevents separation during storage.

The homogenized milk is cooled to 40–45° F. and standardized to comply with U.S. Department of Agriculture standard for evaporated milk. The standardized milk is fed through pin-hole openings into the cans, which are automatically soldered.

The sealed cans are processed under steam pressure at 240–242° F. for not less than fifteen minutes with a twenty minutes' "bringing-up time," immediately after which they are cooled to room temperature. After a short storage time the cans are inspected and labelled.

All the equipment and the entire plant are kept under strict sanitary conditions.

Chemical Composition:—

(*proximate analysis*)	*per cent.*
Total solids	26.1
Ash	1.54
Protein (N × 6.38)	7.2
Fat (ether extract)	7.9
Lactose	9.5

Calories:—

1.38 per gram
39.2 per ounce

Vitamins.—Diluted with an equal volume of water the vitamin A and B (complex) potency approximates that of usual milk.

Micro-Organisms.—The product is sterile.

Claims of Manufacturer.—Libby's Evaporated Milk is clean, easily digestible and contains practically all the nutritive values of ordinary milk, which it approximates when diluted with an equal volume of water. It is [illegible] in infant feeding. The curds formed in the stomach are smaller, softer and those from raw or pasteurized milk. It may be used in cooking and baking as

PACKER'S PINE TAR and OLIVE OIL SHAMPOOS

AMONG many medical men and women, Pine Tar is known to be an effective treatment of all parasitic conditions of the skin. Its use is most serviceable, with infants and children, for the prevention of seborrhœa, eczema, and tinea of the scalp. The Medical Faculty will therefore find Packer's preparations of the utmost value in cases of this description. They include:

Liquid Pine Tar Shampoo for Oily Hair.
" Olive Oil " " Dry "
Pine Tar Soap for Dandruff.

Test sizes of each of these preparations are readily available, free of all cost, to all those medical men who will apply for them, enclosing a professional card, to the Sole Distributors:—

FOOD POISONING—
THE KAYLENE TREATMENT

The following letter has been received.

Messrs. KAYLENE, LTD.

DEAR SIRS,

I am in receipt of your sample of Kaylene, for which I thank you. I do not dispense and do not wish to be without some in the house.

My last sample was used on a patient suffering from acute Ptomaine poisoning following a meal of shell fish (mussel) at 10.30 p.m. Symptoms first appeared at 12.30 a.m., and when I saw him at 3.0 a.m. he was vomiting blood and passing almost pure blood per rectum. He had commenced cramps and nervous twitchings which would shortly have gone on to tonic convulsions. He was very collapsed and had a weak pulse. I gave him only Kaylene in cold water, one drachm every quarter of an hour, from 3.0 until 8 a.m., when I felt it safe to leave him. For the next two days Kaylene was given every one to two hours, and was then followed by Kaylene-ol. No other medication of any sort was used, and he made an excellent recovery. This follows a somewhat similar case which I treated at the end of last year.

Your excellent preparation should supplant Bismuth for any purpose.

Yours faithfully,

Physician to ———. ———, M.B.

IDOZAN HAS BEEN REGULARLY PRESCRIBED BY DOCTORS IN FIFTEEN DIFFERENT COUNTRIES

Effective Ferrotherapy

IDOZAN IS A COLLOIDAL IRON SOLUTION, NEUTRAL, AND CONTAINING 5 PER CENT. OF PURE IRON (Fe).

One teaspoonful of IDOZAN contains 25 ctgrms. of pure iron (Fe).
One dessertspoonful of IDOZAN contains 50 ctgrms. of pure iron (Fe).
One tablespoonful of IDOZAN contains 75 ctgrms. of pure iron (Fe).

Thus, by means of relatively small doses of IDOZAN it is possible—without any inconvenience to the patient—to give much larger doses of iron than could be accomplished with many of the older preparations. In cases of severe anaemia, for instance, one may very well give the patient one tablespoonful of IDOZAN three times daily. This dosage means a daily intake of 2.25 grams of pure iron.

Packings—8-oz. & 40-oz. bottles.

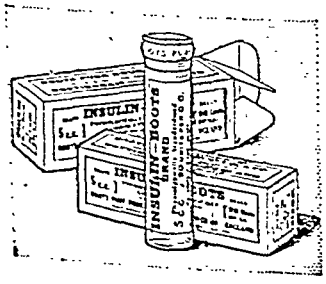
INSULIN (BOOTS)

INSULIN (BOOTS) is prepared in the Laboratories of Boots Pure Drug Company Ltd., under Licence No. 19 (Therapeutic Substances Act, 1925) of the Ministry of Health.



It is made from selected ox pancreas which is subject to the strictest examination before use.

The company possesses specially equipped Analytical, Pharmacological and Bacteriological Laboratories in which all the tests required by the Therapeutic Substances Act are carried out.

Each batch of Insulin (Boots) is tested for potency against the International Standard Insulin and also for sterility—these tests being carried out both before and after filling into ampoules. A sample of each batch, together with a report on the potency and bacteriological tests made, are submitted to the British Medical Research Council whose certificate of correct strength and of sterility is obtained before the batch is issued.

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl-salicylic acid possesses a notable disadvantage. Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach. Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced.

"Alasil" completely overcomes this objection. By combining calcium acetyl-salicylate with "Alocol," unfavourable secondary action upon the stomach is prevented. This beneficial influence is undoubtedly due to the presence of "Alocol" (Colloidol Hydroxide of Aluminium), which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract. "Alasil" is therefore a triumph over acetyl-salicylic acid. It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time. Analgesic, Antipyretic, and Sedative, "Alasil" is indicated in all cases where acetyl-salicylic acid has been used heretofore.

A supply for clinical trial with full descriptive literature sent free on request.

TWO NEW PREPARATIONS

Vide THE LANCET, Jan. 10th, 1931.

"PSYLLA (psyllium seed); LACTO-DEXTRIN (Battle Creek Food Company, Mich., U.S.A., Distributing Agents, Coates & Cooper, Ltd., 41, Great Tower Street, London).—This company have sent us specimens of their laxative agent, Psylla, and their preparation, Lacto-Dextrin, for use in intestinal toxaemia. Psyllium seeds when immersed in water yield a mucilaginous substance which is able to take up relatively large quantities of water to form a gelatinous mass. They become in this way a useful lubricant, while the emollient character of the mass renders it of special service in Fissure or Haemorrhoids. The same firm has received favourable reports from the clinical use of their combination of lactose and dextrin."—*Lancet*, Jan. 10th, 1931.

Samples and literature of both these intestinal products will be sent to members of the Medical Profession on request to Coates & Cooper, Ltd., 41, Great Tower Street, London, E.C.3, Sole Distributing Agents for the United Kingdom and Irish Free State.

Physicians are invited to send for Clinical Reports from Hospitals and General Practitioners in all parts of the world.

For sale by European and American Chemists and Druggists.

Valentine's Meat-Juice Co., Richmond, Vir., U.S.A.

RHEUMATOID ARTHRITIS

UNDER this name, several conditions which are ætiologically distinct are doubtless grouped together, and we are still far from a solution of the cause of the disease.

It is obviously impossible to restore in any marked degree mobility to the joints of the hopelessly crippled, but in the early stages much may be done to retard or stop the progress of the disease.

An eminent surgeon has directed attention to the rôle of chronic intestinal stasis and alimentary toxæmia in the production of the disease, and has emphasised the need for intestinal disinfection.

For this purpose nothing surpasses the use of Kerol Capsules. Kerol is a potent and non-toxic germicide which is unabsorbed from the intestine, so that the whole of its germicidal power is exerted upon the contents of the bowel.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

STANIFORM

Regd BRAND Trade Mark.

METHYL STANNIC IODIDE

OINTMENT
Immediately stops the pain in all cases of burns, scalds, etc

DUSTING POWDER
For application where a greasy substance is counter indicated

LINIMENT
Remarkably effective in treatment of Rheumatoid Arthritis

LOTION
A panacea for Mosquito and other insect bites Most effective for all purposes where Tr Iodine is employed Does not stain the skin and there is no sting

TABLETS
Staniform being an organic compound is more easily assimilated than the Tin preparations at present in use

Supplies may be obtained through the Wholesale Druggists, Druggists Sundriesmen, or Dental Supply Companies

What the Profession says

The following are two recent unsolicited testimonials reported to the Manufacturers by Medical Men

"After using 'Staniform' Ointment in cases of Impetigo and other septic conditions of the skin, I was much impressed by the rapid response to treatment. Also herpes on the lip quickly disappeared after application of 'Staniform' Ointment"

'Festering wound on left heel—when first seen was about the size of a shilling with a good deal of pus Foot much swollen—dressed with 'Staniform' Ointment —healed splendidly in four days"

Similar testimony has been received from a large number of medical men when "Staniform" has been used for the treatment of Burns Wounds, and Skin Ailments

STANIFORM is used in Leading Hospitals.

STANIFORM over a wide field of clinical experience has exhibited powerful curative properties Combining the well known usefulness of Tin in staphylococcic infections with the powerful germicidal properties of Iodin Staniform is indicated generally in local inflammations, inducing an immediate effect with rapid healing

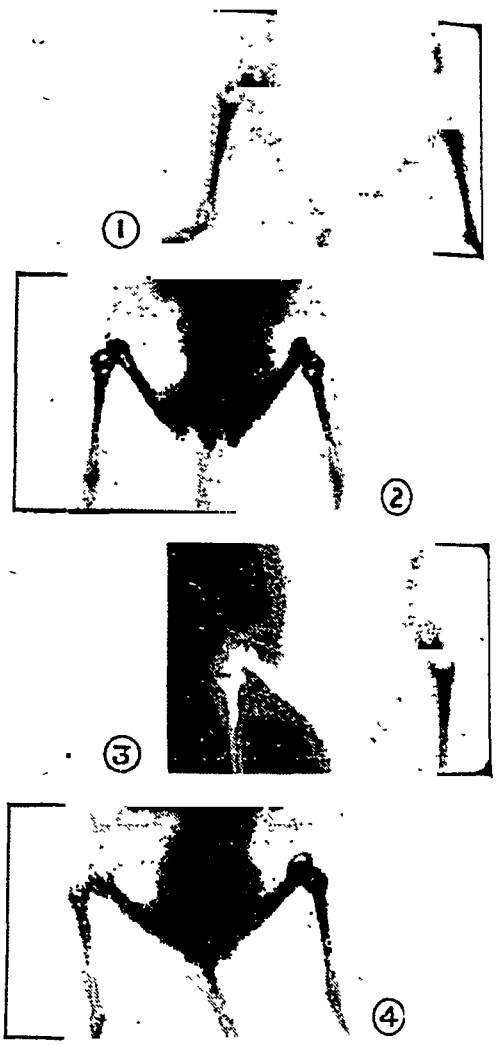
BETTER MILK FOR BABIES

FACTS ABOUT LACTOGEN

Vitamins and Minerals



To fulfil the requirements of the rapidly growing child an adequate supply of vitamins and mineral salts must be provided.

Milk furnishes a sufficiency of these essentials, and in Lactogen their complete conservation is effected.

For the final desiccation of the modified fresh milk the roller process is employed. The heat applied is thus reduced to a minimum and the exposure confined to a matter of seconds.

Lactogen provides a full complement of mineral salts in organic combination, together with the adequate vitamin allowance. It is a complete and balanced diet furnishing the infant with every essential necessary for good health and normal development.

Lactogen is neither a new nor untried product. First introduced in Australia, it has for many years enjoyed a large sale in overseas countries.

1 Rickets (faulty bone development) induced by a deficient diet. Rat A.
2 Recovery in the same rat after Lactogen feeding for 14 days. Rat A.
3 Rickets (faulty bone development) induced by a deficient diet. Rat B.
4 Recovery in the same rat after Lactogen feeding for 14 days. Rat B.
—showing that the antirachitic factor is present in Lactogen in full prophylactic amount.

Lactogen is prepared in England by Nestlés—famous for more than fifty years for the purity of their milk products—from the pure fresh milk of specially selected herds, grazing on picked English farms.

VACCINE TREATMENT
OF
GONORRHOEA

In the treatment of Gonorrhoea the use of Vaccines, in conjunction with the usual routine treatment, materially shortens the course of the disease and prevents complications.

DETOXICATED VACCINES are recommended for preference owing to the massive doses which may be administered with little or no reaction, at the same time achieving great immunity, but where price is a consideration "Ordinary" Vaccines are available at very low prices.

For all early cases of Gonorrhoea, also in cases of Gonococcal Arthritis, Orchitis, Iritis, etc., Gonococcal Vaccine "A" is indicated. This is a pure Gonococcal Vaccine prepared from many strains (Polyvalent).

In cases of more than three or four weeks duration Gonococcal Vaccine "B" is recommended. This Vaccine is composed of equal parts of the above Vaccine "A" and the organisms found as secondary invaders in chronic cases.

Practitioners desiring additional information regarding the above Vaccines and also the special Gonococcal Products for Diagnosis and Test of Cure are invited to write to:

"Chorda" Catgut

Plain and Hardened

Prepared by an improved Iodine process, it passes the prescribed tests for sterility of the Therapeutic Substances (Catgut) Regulations, 1930, *Licence No. 37*

All London Hospital Catgut can be obtained from

Allen & Hanburys Ltd.,

48 Wigmore Street, LONDON, W.1

And all the leading Surgical Equipment Houses

(*Æsculapius*).

ARECAN

(EVANS' NEW LOCAL ANAESTHETIC)

The word ARECAN indicates a series of local anaesthetics specially prepared at Evans' Biological Institute, containing a highly purified form of diethylaminoethyl-p-aminobenzoate hydrochloride, and Adrenalin in various strengths.

ARECAN Solutions are remarkably stable, keeping satisfactorily for an indefinite period; can be boiled without loss of activity and are in themselves sufficiently antiseptic to inhibit the growth of any contaminating organism.

ARECAN Solutions are not subject to the Dangerous Drug Act Regulations, containing no cocaine, and are relatively non-toxic. Three strengths are issued as follows:—

ARECAN LOCAL ANAESTHETIC is a solution containing 2 per cent. diethylaminoethyl-p-aminobenzoate hydrochloride, and Adrenalin 1 in 50,000. It is specially prepared for REGIONAL ANAESTHESIA and diluted is suitable for MINOR SURGICAL OPERATIONS.

ARECAN DENTAL ANAESTHETIC contains 2 per cent. diethylaminoethyl-p-aminobenzoate hydrochloride, and Adrenalin 1 in 10,000.

ARECAN SPINAL ANAESTHETIC contains 5 per cent. diethylaminoethyl-p-aminobenzoate hydrochloride, and Adrenalin 1 in 25,000.

Pernicious Anæmia

TRADE MARK 'WELLCOME' BRAND
LIVER EXTRACT

(An Active Selected Fraction of an Extract of Fresh Liver)

Prepared by a process tested and found efficient by the Medical Research Council. Clinical evidence has established the value of 'WELLCOME' LIVER EXTRACT in pernicious anæmia.

Liver treatment is also indicated in cases of secondary anæmia due to hæmorrhage, such as hæmatemesis or post-partum hæmorrhage; suggested in conditions due to liver dysfunction, in the vomiting of pregnancy and pre-eclamptic conditions and in the anæmia of sprue.

(See Wellcome's Medical Diary, 1931, pages 111-113)

Reduced facsimile

In tubes, each containing an active selected fraction of an extract derived from half-a-pound of fresh liver.

DIRECTION.—
The contents of one tube, or more, daily, in soup or water.

Price in London to the Medical Profession:
32/5 *per box of* 12 *tubes*

INITIAL LETTER FROM A PAGE OF THE VULGATE AS REVISED BY THE ENGLISHMAN ALCUIN.—Alcuin was a Northumbrian of noble birth. He was educated in the famous school of York by teachers who themselves had learned of the Venerable Bede. A born teacher, he became master of the York school, to which flocked students not only from Britain but from the Continent. He enriched its library by manuscripts written in the school itself and by others collected by him in frequent visits abroad. On one of these visits Charlemagne made him promise to obtain permission to spend a long visit at his court at Aachen. Alcuin arrived in the Frankish kingdom in 782, "a man from Britain," they announced, "of the Saxon race, and the most learned man of his time." At Aachen he organised the school of the Palace and became instructor to Charlemagne, his children and his circle.

The initial letter here reproduced is from a manuscript of his edition of the Vulgate, produced at Tours, where he spent his later years as Abbot of St. Martin's monastery.

DATE:—Educational work of Charlemagne and Alcuin began A.D. 782. The MS., A.D. c. 850.

COPYRIGHT

CALCIUM-SANDOZ

$(C_6H_{11}O_7)_2$ Ca.

Unique Advantages:

1.—It is effective. It supplies the physiologically active calcium ion.

2.—It shows distinct superiority in all modes of administration.

ORALLY: It is well absorbed. It is easily administered and does not upset the digestive tract.

INTRAVENOUSLY: It is better tolerated than calcium chloride. The acid-base factor is eliminated.

INTRAMUSCULARLY: It is painless and non-irritating. It is the only calcium salt which can be so administered in adequate doses.

3.—It enables physicians to adequately meet the requirements of any given case.

BY VEIN, for acute need.
BY MUSCLE, to secure intense and prolonged action.
BY MOUTH, for prolonged administration, to meet an increased demand by the organism.

4.—It is completely sufficient in itself as a therapeutic agent.

CALCIUM-SANDOZ is supplied in

Ampoules containing a 10% sterile solution for intravenous or intramuscular injection.
2 c.c. size: Boxes of 10 ampoules.
5 c.c. size: Boxes of 2 and 10 ampoules.
10 c.c. size: Boxes of 1, 5, and 20 ampoules.

Powder for oral administration.—Cartons of 2, 4, and 16 ounces.

Tablets for oral administration.—Each tablet contains 25 grains of calcium gluconate and is especially adapted for division into three parts. Boxes of 30 and 150 tablets. Cartons containing 12 boxes of 30 tablets.

ON
RECENT ADVANCES IN DIAGNOSTIC METHODS IN RENAL AFFECTIONS*

BY
R OGIER WARD, M Ch , F R C S
ISTANT SURGEON ST PETER S HOSPITAL SURGEON WITH CHARGE OF GENITO-URINARY DEPARTMENT, MILLER HOSPITAL

was in 1929 that a most important advance in the gnosis of renal affections was made, and speedily be me established as a method of examination of great lue—namely, excretion urography , that is, the process obtaining photographs of the urinary tract by means substances which, when injected into the blood stream, e selectively excreted by the kidneys, and, inasmuch as ey are opaque to X rays, can be recorded on a photo aphic film The value of this method is at once obvious is useful, therefore, to consider briefly the technique ployed, also the indications for its use, and some of e results that are obtained

Urology is to day very fortunate in the accuracy of ie various means available for diagnosis The cystoscope, st developed into a serviceable instrument in 1890, was ie earliest and greatest advance In 1896 the first diag osis of stone was made by X rays Radiology has made ntinuous progress since then, and there is no reason suppose that the limit of its usefulness is yet approached

Instrumental Pyelography

A great advance occurred when pyelography was stablished in 1906 by Voelcker and Von Lichtenberg This ethod as is generally known, consists of the passage f a cystoscope, and by means of this, of a ureteric catheter p to the renal pelvis and through this slender catheter s run into the pelvis and into the calyces leading from it, ome radio opaque substance Collargol was one of the arliest of these, but to day sodium iodide or bromide is mployed or one of the new contrast substances such s uroselectan Without entering into any detailed escription it may be said that the pyelogram is then nade by allowing the opaque fluid to enter in sufficient uantity to fill the kidney cavities As soon as these re filled pain is felt in the renal angle, and at that moment he process is stopped and the X ray photograph is taken

Instrumental pyelography needs practice and care, ranted these conditions it is a safe and accurate method f examination, and gives very well defined pictures of he renal pelvis, and of the ureter also if the ureteric atheter be withdrawn until its end lies only just above he bladder

When it is remembered that these are photographs, ot of the actual objects themselves, but only of the hadows cast by the radio opaque substance with which he cavities of the kidneys are filled, then we must surely e thankful that the results have the extreme accuracy which we confidently expect, and which is almost in ariably obtained It is a matter for our most generous ppreciation that one of the inventors of the method of nstrumental pyelography, namely, the distinguished urolo gist Professor von Lichtenberg, of St Hedwig's Kranken haus Berlin, is the man who has now developed the method of excretion urography to its present high efficiency, there by making a further and even more valuable advance in the diagnostic methods of renal affections

* Read in opening a discussion in the Section of Surgery at the Annual Meeting of the British Medical Association Eastbourne, 1931

Excretion Urography

Many publications dealing with this important subject have appeared during the last two years, and there is no need to allude to them in any detail now, except to mention that before this success was obtained many attempts had been made to find a non toxic radio opaque substance which the kidneys would excrete with the urine in a concentration suitable for X ray photography Voelcker and Von Lichtenberg realised that this might prove possible and made some experiments in 1905, soon after they had successfully established instrumental pyelography , but these early attempts did not succeed In 1923 Rowntree gave twenty grammes of sodium iodide by the mouth and found that this was excreted by the kidneys, for radio grams showed the bladder to contain this opaque substance, no shadows of the renal pelvis could, however, be obtained Ziegler and Kohler administered sodium iodide with urea by the mouth, and also compressed the ureter to hold up the drug Roseno, before this, had used the intravenous route, injecting a compound of sodium iodide and urea Heritage and myself repeated both these methods and found, as others had, that the pelvis and ureters could be made faintly visible in special cases These attempts, though unsatisfactory, gave clear proof that urography by kidney excretion was a practical method

It was with the assistance of Binz and Raeth, professors of chemistry in the University of Berlin, that the first very successful drug known as uroselectan (5 iodo pyridin N acetic acid sodium) was produced, and has been used by Von Lichtenberg and his assistants in more than 2,000 cases It has been used considerably in this country, and so has a Bayer product, Abrodil Many other chemical compounds have been tried before and after these, but the latest and most successful is D 40, better known as uroselectan B It is another pyridine derivative containing 51 per cent of iodine compared with the 42 per cent in its predecessor, it has been produced by the same chemists and tested in Von Lichtenberg s clinic It is interesting to note that a large amount of iodine is not essential, as only 15 grammes of uroselectan B are used for each injection, compared with 40 grammes of the original uroselectan The special success of uroselectan B is due chiefly to the fact that the kidneys eliminate it in the urine in high concentration and very promptly, namely, in a quarter of an hour, and with a diuresis which is just sufficient to cause it to flow through the urinary tract in an intensity suitable for X ray work Enough has been stated to show that this work has only been brought to success after a great deal of careful research on the part of many different people and with much team work Meanwhile, the two distinguished chemists mentioned are studying the production of suitable bromide compounds in place of iodides, amongst other advantages such compounds may prove to be cheaper

Technique of Injection

A few words as to technique may perhaps be of use Urosclectan needs to be freshly prepared Abrodil and uroselectan B are both sold as sterile solutions the latter in sealed ampoules of 20 c c which contain 15 grammes of the iodine compound, and is the dose used for adults The solution is warmed to body temperature and then injected intravenously , for this quantity a syringe is very suitable There is no need for the injection to be made slowly Naturally, care must be taken to inject it into the lumen of the vein, and serious results have been reported when considerable amounts of some contrast substances (as these compounds are so often called) have been

by mistake injected outside the vein, tissue necrosis having resulted. A syringe with a metal or glass piston will be found suitable; its nozzle should not be placed centrally but at one side, as in the syringes commonly used for injecting N.A.B., etc., and the needle should be a No. 2 hypodermic Record or one of Weintraud's intravenous pattern, 17 gauge, and cut to a short bevel. The needle is best thrust in with the aperture of the bevel facing down towards the skin, since thus it will lie best when it has entered the lumen of the vein; the skin should first be perforated to one side of the vein and the latter pierced with a second movement; this little manœuvre is a much more certain one than that of trying to perforate both skin and vein simultaneously. No tourniquet is necessary if the arm is allowed to hang down for a few minutes before making the injection. An assistant is desirable, though not essential, and should keep the patient's forearm fully extended and thus the veins in the antecubital fossa well exposed, and this is best done by using one hand to support the elbow from beneath it, while with the other the patient's wrist is held down to prevent any flexion of the elbow joint. The patient is then asked to make a tight fist two or three times, and at the same time his upper arm can be compressed with one's left hand in order to obstruct the venous return, leaving one's right hand free for syringe and needle. It is an essential precaution to allow a few drops of blood to flow, or be sucked back, into the syringe before starting to inject; this ensures that the needle's point is in good position within the vein. The syringe must be held quite steady until the injection is complete.

Another method is to employ a similar needle attached to the end of a fine rubber tube, about 3 feet long, with a small glass funnel at the top; in this case it is advisable first to run in a little normal saline, and after the drug, again some more saline to wash it all in. A short piece of glass tubing fitted in the rubber tubing close to the needle acts as a useful window, and thus one can see that no air is allowed to pass into the vein.

The injection of abrodil or of uroselectan B is best made with the patient on the radiological table, for the reason that the first photograph, especially when the latter substance is used, should be taken within a quarter of an hour. This and one subsequent photograph taken half an hour after the injection will often suffice, although, of course, in many conditions further X-rays are required. Some of the films should always include the whole of the urinary tract, others may be confined to special parts of it. Unless it is desired to photograph the bladder when it is distended (and this is not usually the case) the patient must micturate immediately before each exposure, as otherwise the bladder shadow will obscure the lowest parts of the ureters. It is important to prevent this happening, since these should always be very carefully examined; for excretion urography has made possible the special study of this region, and from it there is sometimes much to be learnt.

Contraindications and Precautions

The contrast substances now employed are not broken up in the blood or in any part of the body, and therefore are not dangerous in that respect. Uroselectan produces in some patients a passing but decidedly unpleasant feeling of heat all through the body. Uroselectan B and abrodil produce no discomfort and appear to be entirely non-toxic. Von Lichtenberg's investigations and the researches of his assistants have satisfied him on this point, and have also excluded harmful effects on the mucous membrane of the urinary tract. Many experiments on the isolated frog's heart and kidney have been made with this object and are still being continued. By others, careful researches have been made on the dog, using uroselectan, and no harmful effects have been found to result. Clinically, as has already been stated, over 2,000 cases have been investigated in Von Lichtenberg's practice, and the experience gained there, and by others who have employed these recently produced substances, makes it possible to state with certainty that there exist only very few contraindications to the practice of excretion urography: Of these the most important is uraemia, either present or impending. Therefore, one very obvious precaution to be taken before making use of it, is to estimate the patient's blood urea and kidney function, whenever there is any reason to suspect that renal insufficiency exists. If the kidneys are much diseased, it has been proved by experiment that the liver has to undertake, in part at any rate, the excretion of the drug; therefore the method should not be used if severe liver disease exists. If any serious general illness co-exists then very special caution should be exercised before it is decided to make this examination. Iodine idiosyncrasy rarely manifests itself, and will in any case cease to be a risk if the experiments with bromide compounds are successful. In very acute inflammation of the urinary tract, excretion urography should be avoided. In chronic inflammatory conditions, however, it may be safely employed, and is indeed, in these cases, often of special value.

Elimination of Uroselectan

The experimental work of Hughes and Schaffhauser has shown that uroselectan is chiefly eliminated through the glomeruli. Now it is not the glomeruli but the tubules of the kidney which suffer early and most severely in surgical kidney diseases, especially when obstruction and back pressure exist, the glomeruli being much less affected. Hence, the striking results so often obtained in these cases, for the diseased organ retains the power to secrete the contrast substance in the urine, whilst an obstruction below causes it to accumulate in increasing amount in the pelvis and the ureter. If the renal damage is more severe, then the appearance of the opaque substance is delayed, though when obstruction is also present it sometimes goes on accumulating for a long period after it has been injected. If the kidney is devoid of excretory function then at no time can any contrast substance be demonstrated in that organ. It is obvious, therefore, that excretion urography provides indications of renal function in addition to demonstrating damage to the anatomical structure of the kidney. Now a dense shadow formed by these substances within a kidney may not be evidence of health, but of disease, and often shows in this manner a clear contrast between the sound and the diseased side.

Healthy glomeruli excrete the drug easily, as has already been remarked, and so also healthy tubules ensure that it reaches the calyces promptly; moreover, if the unstriped muscle of the calyces, of the pelvis and of the ureter is intact, both physiologically and anatomically, then the contrast substance is quickly discharged into the bladder so much so that in difficult subjects it may not be very easy to see it in the upper parts of the urinary tract. But, apart from the density of the shadow produced by the contrast substance and the time of its appearance and disappearance, it may be mentioned here that excretion urography makes possible in two other ways the estimation of renal function, namely, by observing the rise in the specific gravity of the urine up to 1,050 or 1,060, which follows the injection within a quarter of an hour to an hour, and secondly by estimating the total amount of the chemical substance found in the urine, a process rather too complicated for general clinical purposes, though of interest because it has been shown that about 64 per cent. of uroselectan B can usually be recovered from the urine.

and that this figure varies with the nature of the disease, being affected specially by the extent to which the glomeruli may have suffered. The variations are, however, also related to anatomical and physiological defects of the pelvis, ureters and bladder, and any considerable hold up of urine by an obstruction will clearly affect the hourly amount of drug available for estimation. Neither of these latter procedures, namely, observations of specific gravity or chemical estimations, will, of course, show the difference of function between the two kidneys. As it is just this discrimination which is so essential in urology, it will be realised that as a measure of function in disease, excretion urography is not a perfect method, for when using it we must depend for this information upon the shadows cast by it, and these may be difficult to interpret, and it will not, therefore, replace the standard and accurate tests carried out with the cystoscope, namely, that of investigating the specimens of urine obtained from each kidney through ureteric catheters and estimating the percentage of urea in them, nor does it necessarily enable us to dispense with infiltration (cystoscopic) pyelography. In some cases it certainly indicates disturbances of renal functions more easily than does the excretion of indigo carmine observed through a cystoscope, as it colours the ureteric effluxes.

Fresh Light on Urinary Mechanisms

One of the most interesting results brought about by this new method of investigation is the fresh light that is shed upon the neuromuscular mechanisms of the urinary tract. Therefore it will help us much in the study of the pathology and treatment of hydronephrosis. This disease is the result of a defect in this mechanism; the law which governs the working of a system of unstriped muscle has broken down, contraction occurs in one segment, but no relaxation in the segment below, probably owing to the disturbance of sympathetic control. The early result of this is a colicky pain, and the later result is distention of the viscus above the offending segment, distension, but not necessarily complete atrophy, of the muscle fibres. This is a most important fact, for upon it depends the success of any operation designed to reconstruct a damaged renal pelvis; instead of adopting the simpler, and, it should be added, according to some authorities the sounder, expedient of nephrectomy. A pyelogram demonstrates clearly a hydronephrosis. Excretion urography sometimes shows the same hydronephrosis but of considerably larger size. This is because in the latter case the kidney has filled the pelvis at a rate to which it is accustomed, whereas in instrumental pyelography the opaque fluid has been run in through the ureteric catheter much more rapidly, and the pelvis has resisted the process. This gives us a clear proof that, though damaged, the pelvic neuromuscular mechanism is not destroyed; and this is an encouragement to the surgeon who wishes to perform upon it a plastic operation. It may be mentioned that this recovery of tone is easily demonstrated in another manner, namely, by draining a hydronephrosis for a few weeks by a nephrostomy; under these conditions it contracts down to a more normal size, just as a bladder distended by an obstruction below contracts down after cystostomy is performed.

The physiology of the pelvis and ureters in a normal subject, though perfectly demonstrated by this method of excretion of contrast substances, requires much study. It is easy to recognise obstruction, because these contrast substances accumulate above it, but in health the drug is quickly swept along in the urine, the calyces are not all full at the same moment, the waves of contraction passing down the ureters cause some segments to be full whilst others are empty, so that the faint shadows are only apparent in a first-class radiogram; and this must be examined very carefully, and with the help of the best form of illumination. The early photographic films are the most suited for this, as later gas accumulates in the intestine and often makes the reading of them very difficult. But already the process is so well established that one may reasonably hope before long to see this study still further advanced by the cinematograph, and above all, by the method of retarded cinema-photography. When this is achieved we shall begin to understand the dynamics of the urinary tract in health and disease.

There are certain conditions in which excretion urography is of special value for other reasons, namely, when it is undesirable or impossible to pass the cystoscope, as, for example, in the presence of a urethral stricture or an enlarged prostate, or severe cystitis. And, again, in circumstances preventing the passage of a ureteric catheter, such as a ureteric kink, or a ureteric calculus. Many other similar surgical conditions might be mentioned, for its striking use in urinary tuberculosis is only one of them. Pyelitis of pregnancy and ectopic kidney are other examples. These are special and important uses, but of less general interest.

We must regard excretion urography first and foremost as a means for the study of the urinary tract as a whole in a manner hitherto impossible. There is no need to claim that it has made unnecessary the standard methods of investigating the urinary tract, or even that it has supplanted pyelography, for this still retains its special value of demonstrating anatomical deformities with unrivalled clearness, and is often usefully combined with the newer method of obtaining shadow photographs. Indeed, excretion urography should not be considered a rival, but rather as a supremely valuable ally.

BURNS AND SCALDS*

BY

ERIC I. LLOYD, M.B., F.R.C.S.,

SURGEON, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET, AND PRINCESS LOUISE HOSPITAL FOR CHILDREN, ORTHOPAEDIC SURGEON, ROYAL NORTHERN HOSPITAL

Deaths from burns and scalds are in this country the subject of a coroner's inquest and, consequently, it may be assumed that the Registrar-General's figures give an accurate picture of the mortality from these accidents. Changing social conditions have done much to diminish the frequency of burns and scalds, and particular mention must be made of the Children's Act of 1908, alterations in lighting, better housing and the trend towards smaller families. Fatalities are certainly diminishing but it must be realised that they still average nearly 1700 per annum in England and Wales.

Burns and scalds are classed together because their lesions are similar but it is a matter of general observation that scalds are a good deal commoner than burns. Donald[2] analysed the London Hospital's figures for the last thirty years and found that the percentage of scalds in the total number of deaths from the combined causes shows a tendency to increase and is now in the neighbourhood of 70. We are thus still faced with a considerable death roll which no doubt is largely made up of young children. Although legislation and social improvements may continue to restrict the number of burns it seems likely that the wastage of child life from scalds will continue so long as the teapot and kettle exert their fascination on youthful minds.

Burns and scalds have always been looked upon as dangerous accidents but it must have surprised many to

* Read in opening a discussion in the Section of Surgery at the Annual Meeting of the British Medical Association, Eastbourne, 1931.

learn from Fraser's Edinburgh series published in 1926 that the mortality was 38.7 per cent. in children under 10 years old admitted to hospital. Prognosis depends upon the area burned and the age of the patient more than upon the depth of the burns. Involvement of 12 per cent. of the body surface may end fatally but an even smaller area has caused death in the very young.

The immediate effect of a burn is to produce shock and this may be the direct cause of death. The clinical picture in no way differs from shock due to other causes, and its effects are due to stagnation of blood in the capillary system throughout the body and a consequent profound fall in blood pressure such as occurs in fainting. When death follows it is consequently death from a physical mechanism. The stage of shock lasts for a variable time and is sometimes surprisingly slight after severe injuries. In the course of some hours, or it may be a day or two, the patient who survives enters a state of toxaemia or else passes on to recovery.

Toxaemia may follow with quite dramatic suddenness at a time when things seem to be going well. The temperature rises to perhaps 104°, the pulse frequency is increased, restlessness supervenes and passes into unconsciousness and death. It has been shown by experiment that this remarkable condition depends upon absorption of certain poisonous substances from the burned area. These substances are protein and amongst them is histamine. Death from toxaemia is consequently death from a chemical mechanism in contradistinction to the physical process which brings about death in the stage of primary shock. These facts must be remembered when we come to treat the two conditions.

General Treatment

The immediate treatment of a burn or scald is the treatment of shock, and attention should thus be focused from the outset on the general condition of the patient. Occasionally it may be wise to postpone removal from the scene of the accident for a few hours, and in such instances morphine hypodermically and fluids by the mouth should be generously given. More often the patient can safely be moved to a hospital or institution and this should be carried out with a minimum of attention to the burned area. Anything that can be done to it under emergency conditions is likely to increase shock and the best routine course is to withhold all dressings. In particular the popular linseed and carron oils should be avoided. A burned patient demands so much medical and nursing care that home conditions are rarely ideal for the treatment of such a case. His prime needs an hour or two after the injury are rest, warmth, fluids and morphine. These should all be supplied as soon as possible and two or three hours may often be advantageously spent in this way before attending to the burns. During this time the patient is given a chance to contend with shock and by making haste slowly he will sometimes avoid disaster.

Local Treatment

Many different applications have been used in the local treatment of burns, but the introduction of a 2½ per cent. aqueous solution of tannic acid by Davidson of the Henry Ford Hospital, Detroit, in 1925 marks an important step forward.

It was known that the dangerous condition of toxaemia was due to the formation of autolytic products of protein decomposition in the burned area and their subsequent entrance into the blood stream. Tannic acid does what the much-used picric acid tries to do, that is to say it coagulates the damaged proteins and prevents their absorption into the circulatory system. In consequence, the constitutional disturbances are minimized, pain is strikingly lessened and scarring is generally slight. Most important of all, there seems good reason to believe that the mortality is greatly reduced. Details of the method and its results have been fully described by E. C. Davidson[1] and later by W. C. Wilson.[2] It will be sufficient here to give a brief outline of its practical application.

As soon as the patient has made some recovery from the initial shock he is anaesthetized with gas and oxygen and the burned area carefully swabbed with ether. Dead and damaged tissue is snipped away with scissors, vesicles are opened and their outer wall removed. A flat, clean surface is thus produced and tannic acid is applied in 2½ per cent. freshly prepared aqueous solution with an ordinary throat spray.

The whole area except the face is thus treated and the patient put back to bed under electric lamps with no other dressing on the burns. The spraying is repeated hourly seven or eight times until the burned area is tanned dark brown. Meanwhile, such toxins as have already entered the system are diluted by copious fluids given by the mouth, rectum, subcutaneously or intravenously.

Subsequent Course after Tannic Acid Treatment

Under this treatment fever and pain subside, the dangerous toxins are locked in a coagulum and the general comfort and well-being of the patient is often remarkable.

If treatment is applied soon after the accident and the toilet has been efficiently performed there may be no sepsis. Sometimes, however, pus forms underneath the scab and fever reappears. Under such conditions there is a temptation to resort to fomentations or other moist dressings. These are harmful because they release the toxins from the inert coagulum and re-establish the condition of toxaemia which we most want to avoid. The proper treatment at this stage is to liberate the pent-up fluid by cutting channels in the coagulum with pointed scissors and so providing mechanical drainage without moistening the scab. During this time the patient remains beneath the electric light cradle which dries up discharge and maintains body heat.

In about two weeks the coagulum spontaneously separates though it takes longer when the burns are deep. Beneath will be found healthy epithelium or granulation tissue. The latter may be dressed with flavine (1 : 1000) in paraffin or with sterile vaseline, since the danger of toxaemia has been removed with the coagulum.

Blood Transfusion

Before the introduction of tannic acid one has seen a timely blood transfusion apparently save life. Robertson of Toronto obtained splendid results by his method of exsanguination-transfusion in which the patient was bled immediately before receiving the transfusion. Though both these methods aim at the dilution of circulating toxins, exsanguination first removes a large amount of toxin and then dilutes the remainder by the blood transfusion.

Prevention is better than cure and it seems reasonable to imagine that if toxaemia can be prevented there will be no need for blood transfusion. Such indeed has been my experience with tannic acid and though there are still occasions—(e.g. in well-established toxaemia) when blood transfusion is a valuable auxiliary method of treatment in burns and scalds, yet nowadays one rarely finds it necessary.

Deformity and Disfigurement

I have said nothing of the deformities and disfigurements which these accidents leave in their wake. Some of my audience may come from industrial areas where their daily round brings them in contact with such cases, and others may recollect unfortunate naval ratings burned

by cordite. My own work in this field of surgery has largely concerned the young and I should like before concluding to touch briefly on this aspect of the matter.

The pictures I show are merely illustrations of the fascinating sideline which we call plastic surgery, a branch of our art which owes much to the patience and skill of Sir Harold Gillies. Opportunities are considerable even though the difficulties in small patients are greater than in adults. Moreover, it is possible that tannic acid will increase their number in much the same way as the introduction of diphtheria antitoxin increased the frequency of post-diphtheritic paralysis by saving the lives of many severely stricken children who would otherwise have died.

Conclusion

In conclusion, I return to our main theme and you will have gathered from my preceding remarks that I gard the introduction of tannic acid as an important ent. Perhaps in the past there has been a tendency forget the excellent adage that we must treat the tient and not the disease. The general treatment of e burned and scalded will always remain of paramount portance and I have failed signally in my task if I have ot brought this home to you. It does, however, seem om our growing experience with tannic acid that we ve in it a substance which treats both disease and tient inasmuch as it forms a local application of first-te efficacy and, when applied early, goes far towards reventing the onset of those calamitous symptoms which e call toxaemia.

Time has not permitted me to cover the whole ground nd though I am highly conscious of the honour of being llowed to open this discussion, I am very well aware hat much remains to be said. In particular, I hope to ear from subsequent speakers whether they find it possible to treat these patients in their private homes; to vhat extent those who have used tannic acid find sepsis lifficult to combat, and how far they use it successfully n late cases as well as early.

INDUSTRIAL PROBLEMS FROM THE STANDPOINT OF GENERAL PRACTICE *

BY

LEONARD P. LOCKHART, M.A., M.D.

MEDICAL OFFICER, MESSRS. BOOTS PURE DRUG CO., LTD., NOTTINGHAM.

The practice of Industrial Medicine is not limited to the problem of occupational diseases. Its frontiers include within them a large area of clinical study common alike to it and to general practice. In order, however, to appreciate these common interests to the full and to devise suitable methods of investigation and study it is necessary to consider not only industrial processes but to an even greater extent to review the whole phenomenon of modern industrialism and the effects which this strange new growth has had, and is having, on the population as a whole. Only in this way can certain otherwise obscure factors be properly evaluated. If the remarks which follow appear in places to be somewhat in the nature of digressions I must ask indulgence for an attempt to outline what I believe to be some important etiological agents in the clinical problems which confront the general practitioner in dealing with industrial incapacity.

Human evolution is the resultant of a continual battle between emerging biological factors and environmental conditions. No history of man; no study of his successes or failures, his health or disease, his hopes or his fears or his mental or physical attributes can be of any value if it ignores the evolutionary value of environment. There have been phases in which the conditions of life have remained more or less constant for long periods, and during these man has been able to adjust himself gradually and on the whole successfully; there have been other phases in which rapid alterations have taken place to which groups of humanity, both large and small, have either failed to adapt or have done so with an inadequate measure of success.

In the last 200 years a wholly new phenomenon has appeared. Man has entered the age of applied science in which for the first time he has deliberately set out not so much to adapt himself to changing environment but by means of his acquired knowledge to modify environment to suit himself. This constitutes an epoch-making break with the past, and the present industrial age is but a stage of this new development. In a bare 150 years man has so changed the face of Western Europe that today in this country over 80% of the population are town dwellers removed from the necessity of direct struggle with nature, relying for their living on industry and commerce and comparatively unmindful of the precariousness and essential instability of their position. Thus the population of Britain is almost entirely dependent on the smooth functioning of a still immature economic system. It is not only surrounded by a mechanised environment of an entirely novel kind but inherited racial memories form no reserve of experience on which man can draw for support in times of difficulty, since biologically the time available for adaptation to new circumstances has in many respects been inadequate as yet to permit of the necessary mental and physical adjustments.

Health, mental and physical, is the measure of successful adaptation to environment and it is therefore less dependent on pathological hazards than we have hitherto been led to believe. Once we get outside the individual, and begin to study the external forces at work on him, we see how important it is to form clear impressions of mental processes; and we see, too, how very subservient physical conditions are to the influences of the mind by means of which alone full personal adaptation can be attained.

When the science of medicine began to supplant the practice of magic its first concern was the body of the sufferer; later the study of community health led to the formation of the public health service which was until recently concerned almost exclusively with physical conditions. As an offshoot of public health administration there has arisen the subsidiary branch of industrial medicine which, by studying and improving the hygiene of factories, workshops and industrial processes, has conferred a great measure of increased health and happiness.

These services are indispensable for the health and well-being of the community and the progress of the past few years must not only be encouraged but in many spheres advances must be accelerated, though the possibility of success along traditional lines is definite and in fact limited, since the psychological factors at work in the community far transcend the purely physical.

The general practitioner has watched official public health activities with much interest even if at times he

* Read in opening a discussion in the Section of Public Health (including Tuberculosis and Occupation Diseases) at the Annual Meeting of the British Medical Association, Eastbourne, 1931.

has begun to wonder where, in a not far distant future, his own sphere of usefulness will lie, ground as he feels he is between the upper millstone of clinical specialism and the nether one of administrative medicine. The day of the general practitioner is, however, not waning but only dawning. In his hands lies the ultimate responsibility for co-operating with the public health services in extending the boundaries of their mutual spheres in order to produce the harmonious integration of those mental, physical and spiritual factors whose combination forms the only possible basis for the intellectual growth and adaptive development of the industrial West.

Health is essentially bipolar, it has a physical pole and a mental pole and only in a correctly balanced appreciation of both can we truly assess the biological problems of man as a whole and see them in proper focus against the background of modern western mechanistic, or industrial, civilization. This constitutes a field of study of supreme importance to the general practitioner.

We must consider briefly three aspects of this new orientation of medicine. First, the chief phenomena of cultural and environmental development; secondly, the reactions of man to these forces; and, thirdly, the means necessary in order to achieve a greater measure of individual and community health which is, as we have seen, nothing more than a proper system of adaptation, resulting in the fully integrated man at home in his environment and endowed with adequate means for modifying it to his needs and where this is impossible modifying himself to it.

Without doubt the outstanding element in a mechanistic civilization is the power that lies in human hands for modifying and controlling the forces of nature. This is the direct result of the application of scientific knowledge to economic problems. It has developed rapidly into an immense power quite beyond the ability of single individuals to control, and as a result an intricate and highly complex system of co-ordinated action has been evolved in which in innumerable ways the individual is subordinated to the community, the man is merged in the citizen and the personal is incorporated in the impersonal. In the agricultural and pre-agricultural age the terrifying forces of nature necessitated rationalizing explanations based on the assumption that the tribal god was by such means manifesting a power of arbitrary interference which could be averted only by propitiation and sacrifice. In the industrial age these natural forces do not affect the town dweller to any marked degree and he has been taught to look upon them for what they really are—namely, effects produced by causative agents operating under immutable natural laws; and since, too, he has been endowed with means of dealing with them by economic, scientific and material weapons the old claims of instinctive and primitive theology have to a large extent ceased to exert their influence over him. Nevertheless racial memory dies hard and in our modern world there are [illegible] endless relics of primitive magic—charms and taboos—have no claim in reason but which exert their in[illegible]hr[illegible]h the operation of inherited feeling states. Many different [illegible]e as an instrument of divine wrath has, treatment of burns, [illegible]ced by a new fear—that of the com- aqueous solution of tandern life which crushes remorselessly Ford Hospital, Detroit,' homage. Fear, sense of inferiority forward. [illegible] be confused with rational con-

It was known that the da[illegible] religion throughout the ages, was due to the formation of [illegible]t influences at work in our decomposition in the burned [illegible]nder modern conditions to entrance into the blood stream. [illegible]of individuality, and to the much-used picric acid tries to [illegible]us to clutch fearfully coagulates the damaged proteins [illegible]and from our grasp. absorption into the circulatory system. [illegible] environment of the constitutional disturbances are minimito the terrible congestion of the towns which bequeathed to us a l[illegible] of slums and human damage, but of recent years th[illegible] power of industry has been directed towards a progress[illegible] amelioration of the physical conditions of life. We f[illegible] our people better fed, housed and clothed than ever before; science has tackled disease and the economic conditions of the wage earner have been greatly improved. Such eloquent figures as those for expectation of life, infant mortality and tuberculosis indicate most forcibly that physical improvements have reacted favourably on the health of the community. When, however, we come to study the *cost* of sickness and the *amount of time* lost due to it, we find a very serious state of affairs. Sir Walter Kinnear has recently referred to the "almost inexplicable increase in the rate of sickness" and in point of fact at first sight it certainly does appear inexplicable that in the ten years 1920–1929 the increase in lost time should have been so great. During this period for an increase of but 10.2% in the number of insured persons, from 13,579,000 to 14,963,500, there has been steady and progressive increase in lost time as follows:

Year	Lost Time in Weeks (approx.)		
	Sickness	Disablement	Total
1920	9,988,500	4,077,500	14,066,000
1929	16,000,000	13,500,000	29,500,000
Increase ...	60.2 %	231.1 %	109.7%

Long absences absorb more time than formerly by 231.1%, while absences of less than 26 weeks account for the much smaller but still very large increase of 60.2%. It is impossible to believe that the physical condition of our population has deteriorated at this alarming pace and I suggest as explanation that the increased sickness is largely psychogenic and reveals the existence of a state of mind which must be more widespread and productive of a vastly greater amount of latent incapacity than is manifest in the figures for actual absenteeism, since it must be remembered that these figures take no account of sickness of less than three days' duration nor of the periods of relative inefficiency preceding and following absence from work. The figures with which we are now dealing represent actual incapacity which must always be looked on as an end-result of a failure of preventive or therapeutic measures. The blame for this rests as I think largely with a system of education which still pays far too little attention to the mental and intellectual growth of the child and far too much to the mere inculcation of knowledge.

When one reviews medical certificates it is impossible not to be struck by the number of such conditions as "nerves," "neurasthenia," "debility," and "anaemia," while clinical observation shows an increase in intractable dyspepsias, many dermatoses, enteroptosis, cardiac irregularity, neuralgias and countless other symptoms for which on careful physical examination no organic basis can be found, and it is, I think, impossible to resist the conclusion that at least a prima facie case has been made out for reviewing the whole matter *de novo* from a psychological standpoint.

It is my object to suggest certain etiological factors for this serious medico-economic problem and to offer tentative proposals for a method of dealing with it, because if this widespread increase of sickness is due to psychogenic causes, then as a nation we are suffering from neurosis on the grand scale and if we wish to hold our own in the modern industrial world we must do something about it not only effectively but at once.

It may be helpful to enumerate some of the possible causative agents of community ill-health and by placing our patients against the background not of individual industries but of industrial civilization to see how man tends to react to it.

The vast machine of modern life is at times a terrifying thing. It even looms larger to many than did the old idea of a wrathful and avenging Deity, and I think there is little doubt that the present restless craving for sensation, pleasure and vicarious eroticism is no more than an overcompensation for a very widespread, if unconscious, appreciation of this fact. In the face of such forces as unemployment; mechanical displacement of labour; the competition of girls with men and the success of the former in handling machines and in executing small repetitive processes at lower cost; the economic difficulties of the home and the resulting problems of sexual adjustment, there is a tendency for many, and males especially, to develop a feeling of inadequacy to life which is liable to be rationalized in consciousness as illness rather than to be acknowledged frankly for what it really is—namely, a fear of the unknown and the intangible. The pressure at which modern business is conducted and the anxieties and worries of this very difficult time can produce nervous strain to a marked degree, and the very fear of being ill further tends to increase the difficulties of both doctor and patient even in respect of purely physical diseases.

In the homes we find economic difficulties in the way of early marriage leading to anxiety neuroses in the young; we find, owing partly to the competitive raising of the standard of living, married couples labouring under the most serious financial difficulties once their families exceed a very definite maximum number; and we find, too, that in the absence of proper teaching on sex hygiene and contraception there are very serious disorders of the love-life—the basis on which the well-being of any community must ultimately rest.

In industry compensation for accident and disease is being sought as an end in itself rather than as a means towards restored function, and the result is not only to burden the employer unduly but to militate against the best interests of the workman. Owing to a failure to appreciate the full significance of personal idiosyncrasy, in which the mental factor is a very large one, conditions are often ascribed to occupation which strictly speaking are no more than the hazards of an every-day life pregnant with vast possibilities for the development of such states.

In the sphere of health education there has been a very serious secondary effect which few could have foreseen. In addition to the increasingly sound teaching in elementary hygiene in schools, which is doing much to improve the physique of our adolescents, there is a spate of health propaganda in the lay press partly in the form of articles, [illegible] masquerading as "news," which is having the effect [illegible] introspection and an undue concentration on [illegible] purely [illegible] factors [illegible] reactions [illegible] with much [illegible] physi[illegible] is a great strain on man, not so much by [illegible] as by reason of the short time, biologically [illegible], that has been available for him to make the necessary readjustments. The pace is fast and it is increasing, and we must face the whole problem frankly and ask ourselves what we can do to restore the balance. It seems as if we must include within the definition of public health a large tract of knowledge and study hitherto regarded as quite outside its scope, and it is along these lines that I believe the solution is to be found which shall lift our industrial civilization out of the swamp in which it is at present in danger of foundering.

In the face of the problems of modern life there appear to be two outstanding reactions of the mind—fear and the sense of inferiority. It is impossible to estimate to what extent fear is present in the minds of the industrial masses but there can be no doubt that it is a most powerful factor. Machinery in this transitional period has without doubt contributed temporarily to the total of world unemployment. There is a surfeit of manufactured goods and of cheap raw materials, and while it is probable that this difficult phase will in time pass we are to-day faced with the paradox of millions in want largely because there is too much merchandise in the world, and, since no one really understands why this has all come about, fear of an inexplicable situation is widespread.

Fear is manifested *inter alia* as fear of mechanism, fear of economic forces, fear of war and an unreasoning fear of losing religion which too few are as yet either able or willing to dissociate from primitive and mediaeval systems of theology.

Inferiority, which in varying degrees is an attribute common to us all, is a relic of our racial reactions to the "Father-Image" which in present-day life is represented for us by Authority, be it ecclesiastical, governmental, educational or economic. The patriarchal system is by no means dead and it still operates to prevent individuals from working out their own destinies, thinking their own thoughts and standing on their own legs. It tends to produce in children a dull normality and in adults dependence on omniscient authority to protect us from the pitfalls of life, and it tends also to so prop us from cradle to grave that the vitalizing sparks of individual personality and responsibility are, among large classes of the community, in danger of being extinguished.

Unemployment is disastrous to the body and mind, not only among those who are actually out of work but among those who wonder whose turn it will be next. Whether we have 2½ millions entirely workless or 25 millions in work for shorter hours the inevitable result of mechanization is and will be an increase in non-working time. This can be styled unemployment or leisure—it all depends on how wide the process is spread. The use of machinery in modern economic life undoubtedly means less man-hours of work, not as a mere humanitarian stunt but as a necessary corollary to a situation which 25 years ago very few could have visualized, but the adjustment calls for concerted action on an international basis.

Education in the right use of leisure is therefore an urgent necessity unless leisure is to be allowed to degenerate into pathogenic idleness, a foretaste of which is already evident in our sickness statistics

The present economic situation is producing a wholly novel set of problems which include *inter alia* anxiety and apprehension as to the stability and permanence of work which no system of mere monetary payment can alleviate; the need for the limitation of families; the difficulty of providing for old age and incapacity; a sense of inadequacy to the demands of a complex life; and a demand for a new set of values against which to place, compare and judge new needs, new satisfactions and new frustrations.

It is necessary at this point to consider what is, I believe, a vitally important matter. Scientific methods of investigation applied to formalized religions have exposed many theological fallacies, have in fact demolished countless spiritual props and left men wondering where it will all lead to. Many people fail to realize that religion and dogmatic theology are distinct and different and that natural intimate and personal religious experience, which is a supreme and vital human necessity, is unaffected by the demolition of theological dogma Large numbers of men and women are afraid that in rejecting theology they must dispense with religion as well, and they thus tend to lose faith in the future because, being endowed with insufficient independence of judgement, they are unable to devise an individual and personal philosophy. To lose

faith in the future, to be unsure of oneself, and to doubt the sublime realities of spiritual experience are matters of grave importance as regards man's ability to integrate himself and adapt harmoniously to his environment. But the fact remains that while science has revolutionized the economic life of man it has also gravely disturbed his spiritual life, and in the latter case the disturbance is due to the fact that man has failed to appreciate the aims, methods and limitations of scientific investigation, and has confused its legitimate application to theology with its complete dissociation from personal religious experience.

All these factors are important not only as sociological phenomena but as fundamental issues in the question of individual and community health. I believe that in a study of human psychology along these lines we can discover the key to our industrial and commercial problems, remembering always that commerce, the mainstay of our lives, rests *au fond* on faith and credit which Sir Josiah Stamp believes to be mainly psychological phenomena. Careful interrogation of patients suffering from the conditions previously enumerated will bring to light case after case which exemplify the various points just mentioned. It would be foolish to press the point too far but if only a case is made out for further research along these lines my object will have been attained.

I believe that the future of the public health lies as much in the hands of general practitioners as it does in those of Medical Officers, and for this purpose both must make a study of industrialism and of human psychology—not so much in order to practise psychotherapy as to understand why men act and react as they do.

With regard to constructive proposals. The bulk of the general practitioner's time and effort must of necessity be concentrated on treating the sick though from the point of view of the community preventive medicine is of the utmost importance. Nobody can be indifferent to it, but if most of the doctor's time has to be spent in treatment how can he take a share in prevention? I believe it can be achieved by collaboration with those who have facilities for training the minds of both young and old but who are as yet outside the boundaries of preventive medicine. First and foremost, educationists, teachers and parents; secondly all who give spiritual guidance and will adapt their teaching to modern needs; and thirdly all who are engaged in the handling of men and women in industry. Stated in few words their task amounts to this: to teach, encourage and instruct everyone, especially the young, how to grow intellectually as individual men and women, self-dependent and, as Aristotle says, self-sufficient, solving their problems by constructive thought rather than by second-hand formulae. Dr. Charles Richet, the famous French physiologist, in his book *L'homme stupide* has shown how since the emergence of man he has generation after generation taken the beliefs of his forefathers, modified them but slightly and handed them on, so that to-day the mass of mankind acts and thinks not as rational beings reacting directly to their environment but as puppets of racial memory bound by tradition, shackled by prejudice and dependent on the good opinion of the mass of their fellows. It seems as though man has conspired against himself to close his eyes to truth. It is now possible, however, largely through the inspiring influence of science to blow a breath of fresh air through many ancient conceptions and to realize that nothing can save man but man himself.

Man has been propped by theology: dogma is collapsing and he finds himself in the dark, prey to fear and to neurosis. Here the Church can help to set him on his feet, show him the way to develop a dynamic religious philosophy of the simplest kind and by restoring his morale encourage him to spiritual growth and mental health. Children have for too long been filled with information and their creative individuality allowed to wilt in the process of moulding them into model citizens and standardized types. The love of truth has been encouraged in them so little that the Headmaster of Harrow has recently been led to assert that accuracy of thought is an attribute of few outside the followers of the exact sciences.

In the face of ignorance we cannot deal adequately with great and pressing problems, ever increasing in complexity and ever changing in their appearances. It is necessary to go to the heart of our modern civilization and from our study to evolve stable judgements by which our people may be enabled to react more harmoniously and rhythmically to their environment. Out of such adaptations sound health alone can flow. Nothing, I submit, is more urgent than the widespread cultivation of a scientific conscience; namely, to observe honestly, classify carefully, evolve reasonable hypotheses and test these fearlessly against facts in the evolution of new laws of life. This is an ideal which can be modified to suit the most meagre intellects.

Since adequate treatment for psychoneuroses is economically impossible except for a minority of cases the future of medicine appears to me to rest largely in the therapeutic and preventive power of educational influences.

Of recent years much work has been done in studying the psychological problems of specific industries and occupations. The Industrial Health Research Board and the National Institute of Industrial Psychology have in many directions broken new ground, but the larger problem, that of industrial civilization and its effect on individual and corporate health, has so far been rather neglected. These matters concern the general practitioner but they also call for radical changes in our system of public education.

In industry steps are being taken slowly but surely to establish clinics within factories. These can not only treat industrial accidents and occupational illness but can do something to attack the mass of psychogenic incapacity which masquerades under such a large variety of labels. The industrial clinic either in a large factory or in connection with a group of smaller ones, can be a very important link in the chain of public health work, but it can only serve its true purpose by collaboration with general practitioners and educationists.

If there is one particular point that I would desire to emphasize in this paper, it is that the burden of sickness—which is not only causing vast loss of time and money by actual absence but which is also sapping the general vitality of a far greater number than those who actually "go sick"—is in the main a psychological problem, and it is necessary for us all, whether we consciously practise psychotherapy or not, to grasp some at least of the essential workings of the mind which modern psychopathological research has unfolded before us. Armed with this knowledge a vast amount of successful work can be accomplished on the very simplest lines without embarking on the dangerous and highly technical sea of analysis or the more difficult forms of psychotherapy. Working on simple lines my own sickness records for the past five years show a steady decline in lost time from psychogenic causes from 1921 working days per year per 1000 workers in 1926 to 822 working days per 1000 in 1930. The results are hopeful and I believe significant of what we can achieve.

Modern industry can be either the means towards our higher destiny or the agent by which western civilization is ultimately to be drowned in the sea of its own complexity. It rests with educational and medical science and especially with those engaged in general practice to direct the course which we are to pursue, relieve us of the great burdens of invalidity and incapacity, and so enable industrialized man to take his place as an integrated individual in the eternal scheme of things.

THE INCIDENCE OF TUBERCULOUS INFECTION AND ITS RELATION TO CONTAGION IN CHILDREN UNDER 15

An Analysis of 1,220 Children from the Brompton Hospital Research Department

BY

DOROTHY J. DOW, M.A., M.B., Ch.B. AND W. ERNEST LLOYD, M.D., M.R.C.P.

Last year we published a report on tuberculosis mortality in children[1] which included the results of an investigation into the fate of 1,192 children born of parents who had attended the Brompton Hospital, London. This work has been followed by an investigation, also at the Brompton Hospital, into the incidence of tuberculous infection in children and its relation to contagion. The figures deal for the most part with families of an urban working-class population. All children under the age of 15 attending the hospital have been tested, together with a number of contact children.

The majority of workers in tuberculosis are of the opinion that, from the standpoint of accuracy, the quantitative intracutaneous test of Mantoux is the best for determining tuberculous infection. However, as extensive work has been recently done in America and Norway with the Pirquet test, we carried out a preliminary investigation on just over two hundred children with this method before going on to the main part of our work—that is, an investigation of one thousand cases with the Mantoux test. We have thus been able to give our opinion as regards the delicacy of the two tests.

The Pirquet Test

The flexor surface of the left forearm was cleaned with ether; a drop of Old Tuberculin—Human (T)—was dropped on to the skin from a pipette and the skin under the drop was incised with a vaccination lancet. The size of the scratch and the amount of tuberculin used in each case was approximately the same. The arm was left exposed to the air for at least fifteen minutes. The child was seen in forty-eight hours and any reaction at the site of the test was noted. To begin with, a control was always done on the opposite arm, but as no reaction ever occurred with it this was given up as being unnecessary.

The results are given in five-year age groups in the following table.

Table I

Age.	Number of Cases	Number Positive	Per cent. Positive
0-5	52	7	13.5
5-10	130	34	26.2
10-15	35	18	51.4
0-15	217	59	27.2

Our figure of 27.2 per cent. agrees closely with that of Chadwick and Zacks,[2] who tested 101,118 school children and found that 28 per cent. gave a positive reaction. The above 217 cases were further divided into three classes: (1) Children who had lived or were living in contact with a person or persons suffering from pulmonary tuberculosis with positive sputum (Contact T.B.+). (2) Children who had lived or were living in contact with a person or persons suffering from pulmonary tuberculosis who had no sputum, or in whose sputum tubercle bacilli had never been found (Contact T.B.−). (3) Children who had never lived in contact with a tuberculous person as far as was known (No contact). Results are shown in Table II.

Table II

Age	1. Contact T.B. +			2. Contact T.B.−			3. No Contact with Tuberculosis		
	Number Tested	Number Positive	Per cent. Positive	Number Tested	Number Positive	Per cent. Positive	Number Tested	Number Positive	Per cent. Positive
0-5	20	5	25.0	15	2	13.3	17	0	0
5-10	53	23	43.4	27	3	11.1	50	8	16.0
10-15	7	4	57.1	11	5	45.5	17	9	52.9
0-15	80	32	40.0	53	10	18.9	84	17	20.2

It will be noted that twice as many children under the age of 15 are infected with tuberculosis when in contact with a person with positive sputum as compared with the other two groups. This fact will be dealt with more fully later

The Mantoux Test

Having examined 217 children with the Pirquet test, we applied the intracutaneous test of Mantoux to 1,003 children. For this purpose a sufficient quantity of Old Tuberculin of one brew (T. 1586) was kindly supplied by Dr. O'Brien of the Wellcome Research Laboratory, to whom we are grateful for many suggestions. Dilutions of (*a*) 1 in 10,000 tuberculin, (*b*) 1 in 1,000 tuberculin, and (*c*) 1 in 100 tuberculin, were made in sterile water to which had been added 0.5 per cent. phenol. The dilutions were always freshly prepared.

A 1 c.cm. glass Record syringe fitted with a No. 214 needle (Burroughs Wellcome) was used, and 0.1 c.cm. of 1 in 10,000 tuberculin was injected into the skin of the flexor surface of the left forearm. The site of injection was examined after forty-eight hours, and any reaction was carefully noted. If no reaction had occurred, 0.1 c.cm. of 1 in 1,000 tuberculin was injected intracutaneously, and the arm was again examined in forty-eight hours. If this was still negative, a third

Table III

Age	Boys			Girls			Total		
	Number Tested	Number Positive	Per cent. Positive	Number Tested	Number Positive	Per cent. Positive	Number Tested	Number Positive	Per cent. Positive
Years 0-1	0	0	0	0	0	0	0	0	0
1-2	2	0	0	2	0	0	4	0	0
2-3	17	3	17.6	14	1	7.1	31	4	12.9
3-4	25	5	20.0	14	7	50.0	39	12	30.8
4-5	43	11	25.6	22	5	22.7	65	16	24.6
5-6	67	15	22.4	56	15	26.8	123	30	24.4
6-7	63	26	41.3	52	25	48.1	115	51	44.3
7-8	61	24	39.3	45	19	42.2	106	43	40.6
8-9	54	23	42.6	34	14	41.2	88	37	42.0
9-10	68	28	41.2	38	21	55.3	106	49	46.2
10-11	52	22	42.3	39	21	53.8	91	43	47.3
11-12	40	25	62.5	33	18	45.2	73	43	54.4
12-13	29	19	65.5	22	15	68.2	51	34	66.7
13-14	34	17	50.0	26	16	61.5	60	33	55.0
14-15	21	17	81.0	24	20	83.3	45	37	82.2
0-5	87	19	21.8	52	13	25.0	139	32	23.0
5-10	313	116	37.1	225	94	41.7	538	210	39.0
10-15	175	100	56.8	150	90	60.0	325	190	58.3
0-15	576	235	40.8	427	197	46.1	1,003	432	43.1

injection of 0.1 c.cm. of 1 in 100 tuberculin was made and examined in forty-eight hours, and any reaction noted.

Many workers, both in this country and abroad, regard 1 c.cm. of Old Tuberculin as being equal to 1,000 mg., and classify their results of the Mantoux test according to the reaction to:

0.01 mg (0.1 c.cm. of 1 in 10,000 O.T.);
0.1 mg. (0.1 c.cm. of 1 in 1,000 O.T.); and
1 mg. (0.1 c.cm. of 1 in 100 O.T.).

We agree with Bandelier and Roepke[6] that the milligramme notation should be entirely dropped, and all results should be recorded according to the dilution of the O.T. used.

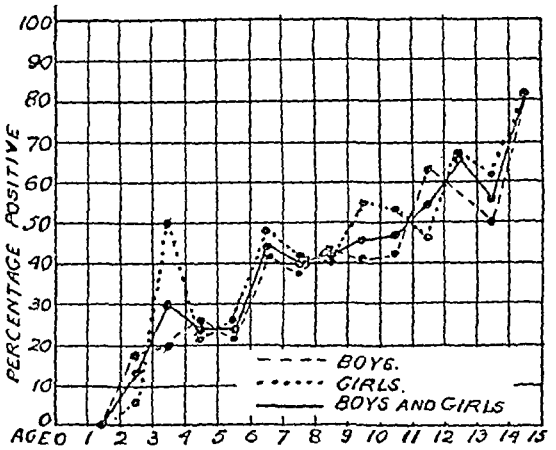

FIG. 1.—The percentage of children who reacted to the Mantoux test according to age and sex groups.

For various reasons it was not found possible to do the three tests in all the children. No difficulty was experienced in carrying out the tests even with the youngest; compared with the Pirquet method the technique of the Mantoux test is, if anything, simpler. The results are given in Table III and Fig. 1.

The foregoing graph, although somewhat irregular, shows that the incidence of tuberculous infection increases gradually from infancy to the age of 15. This irregularity of the graph becomes less obvious by grouping the children into larger age groups.

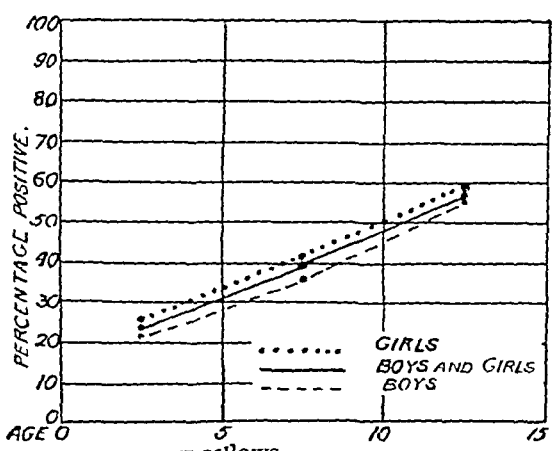

FIG. [illegible] ...ldren in different age groups ...ellows.
[illegible] ...rcentage of chi... who reacted to the Mantoux test.

From this it will be seen that ...23 per cent. of children ...etween 5 and 10 years, from birth to 5 years, 39 per cent. ... years old have been and 58 per cent. between 10 and 15 ...ome time or other, infected by the tubercle bacillus at ... ...erculous infection From our figures the incidence of tu... 5 years is 43 per in children between the ages of 0 and ... 23 children, 279 ...nt. It should be added that of the 1,0... these figures had been exposed to tuberculosis. Comparin... me... are rather with those of other workers, we find that they ... based ower than those of Opie and McPhedran,[3] ...

their results on a large number of school children in Philadelphia, while they are higher than those of Dick[7] and Seitz,[1] working in San Francisco (Fig. 3).

As already mentioned, we found it impossible to test every child with 1 in 100 tuberculin, and so it is not unreasonable to suggest that the number of positive reactions would have been somewhat higher if this had been done. Of the 1,003 Mantoux tests which were performed in children under 15 years of age, 268 children, or 26.7 per cent., were positive to 0.1 c.cm. of 1 in 10,000 tuberculin. Of the 735 who were negative, 668 were re-tested with 0.1 c.cm. of 1 in 1,000 tuberculin, and of these 122 were positive. This brings the number of positives up to 390,

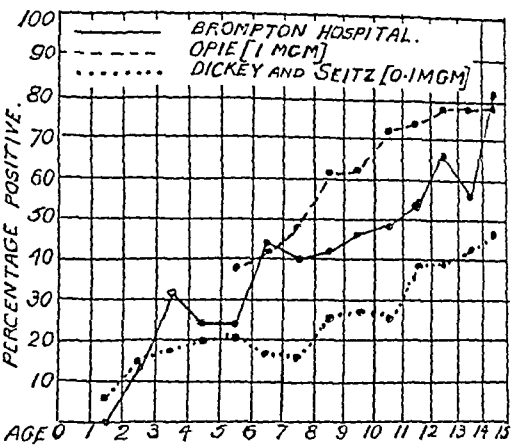

FIG. 3.—The percentage of children at different ages who reacted to the Mantoux test, as given by various workers

or 38.9 per cent. Now if all the 735 who were negative to 0.1 c.cm. of 1 in 10,000 tuberculin had been re-tested, instead of only 668, the number of positives would presumably have been 402, or 40.1 per cent., an increase on our figures, so far, of 1.2 per cent. Of 421 tested a third time with 0.1 c.cm. of 1 in 100 tuberculin 42 were positive, making a total of 432, or 43.1 per cent.—the figure which we gave as showing the incidence of tuberculous infection in children up to the age of 15. If all the 601 who would have been so far negative to 0.1 c.cm. of 1 in 1,000 tuberculin had been tested with 0.1 c.cm. of 1 in 100

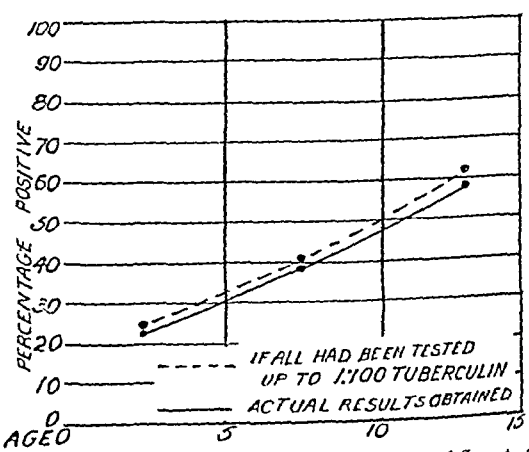

FIG. 4.—The percentage of children in different age groups who would presumably have reacted to the Mantoux test if all had been tested up to 1 in 100 tuberculin, compared with our actual findings.

tuberculin, 60 would presumably have been positive, making a total of 462, or 46.1 per cent. We may therefore say that the incidence of tuberculous infection in children up to the age of 15 attending the Brompton Hospital is somewhere in the region of 46 per cent. This figure may be adversely criticized as being too high for the general population of this age, because this is a special hospital for diseases of the chest, and for this

eason more children exposed to tuberculosis, or suspected if being tuberculous, are brought for examination.

It will be noted that the figure 26.7 per cent., which epresents the percentage of children under 15 who are ositive to 1 in 10,000 O.T., is practically the same as the 7.2 per cent. positive when the Pirquet method was used. This agrees with the conclusion reached by Happ and Casparis[5] about the two tests. By using 1 in 1,000 O.T. the number of positives was increased from 26.7 to 38.9 per cent., which makes a large difference in results, and by still further using 1 in 100 O.T. a further increase of 4.2 per cent. was obtained, making a total of 43.1 per cent., which would have been still higher (46.1 per cent.) if all had been tested up to this amount. From this it appears that by using the Mantoux test rather than the Pirquet, more accurate results are obtained in estimating the incidence of tuberculous infection, while the Mantoux test has also the advantage that a fixed amount of tuberculin is used in each case. Our figures show that the incidence of tuberculous infection in girls is slightly higher than in boys (see Figs. 1 and 2).

Analysis of Contact and Non-contact Groups

We have further subdivided our cases into the same three groups which were mentioned when dealing with the Pirquet test. The results for these three groups are given in Table IV and Fig. 5.

Table IV

Age	1. Contact T.B.+			2. Contact T.B.−			3. No Contact with Tuberculosis		
	Number of Cases	Number Positive	Per cent. Positive	Number of Cases	Number Positive	Per cent. Positive	Number of Cases	Number Positive	Per cent. Positive
0–5	21	15	71.4	15	3	20.0	103	14	13 6
5–10	87	66	75 9	47	18	38.3	424	126	31.2
10–15	76	58	76.3	33	14	42.4	217	118	54.4
0–15	184	139	75.5	95	35	36.8	724	258	35.6

The results show that up to the age of 15 twice as many children living in contact with a person suffering from pulmonary tuberculosis with positive sputum are

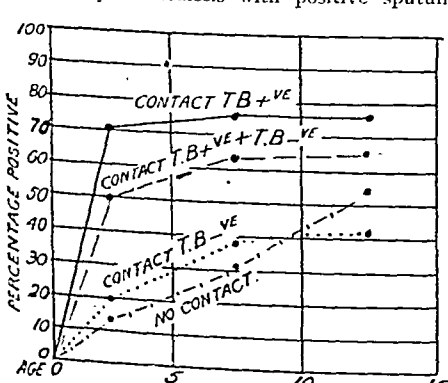

Fig. 5.—Percentage of contact and non-contact children who reacted to the Mantoux test, arranged in age groups.

infected with tuberculosis as compared with those children living in contact with a person with pulmonary tuberculosis with no sputum or negative sputum, or where there is no known contact with the disease, the figures being 75.5, 36.8, and 35.6 per cent. respectively. It is noteworthy that there is no marked difference between the curves of children in contact with parents diagnosed as suffering from pulmonary tuberculosis, but with negative sputum, as compared with the non-contact group.

In considering the three age groups 0–5, 5–10, and 10–15 years, a very striking difference in the graphs of the contact and non-contact cases will be observed. These show that the percentage of positive reactors in the children exposed to open tuberculosis is almost identical

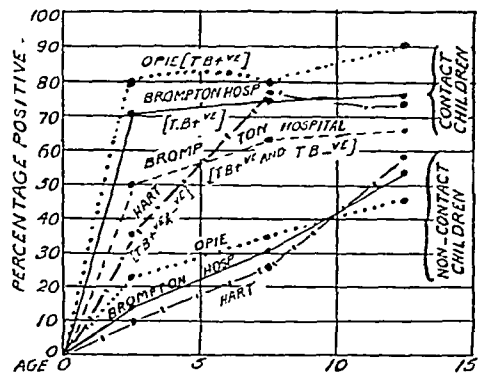

Fig. 6.—Percentage of children in contact and non-contact groups who reacted to the Mantoux test, as given by various workers.

in the three age groups, the average being about 75 per cent. On the other hand, the percentage of positive reactors in the non-contact children increases steadily with each age group. In the 0–5 year age group, the percentage of positive reactors is five times higher in children in contact with open tuberculosis than in the non-contact children.

These findings agree very closely with those of Opie and McPhedran[6] and Schlesinger and Hart[7] as is shown in Fig. 6. Opie included those children living in contact with open tuberculosis, while Hart included all children living in contact with all forms of pulmonary tuberculosis.

The group of children living in contact with a person with tubercle bacilli in the sputum was further analysed according to the relationship of the contact.

Table V

	Number of Cases	Number Positive	Per cent. Positive
1. Mother T.B.+ (father healthy) ...	50	34	68.0
2. Father T.B.+ (mother healthy) ...	74	57	77.0
3. Both parents T.B.+	4	4	100.0
4. Mother T.B.+ father T.B.− ...	2	2	100.0
5. Other contacts T.B.+	54	42	77.8

The above figures show that children exposed to a tuberculous father with positive sputum react more frequently than children exposed to a tuberculous mother with positive sputum. Although the difference is only slight, it is of interest to note that in our previous report[1] we found that the mortality rate from tuberculosis was greater in the children of fathers with positive sputum than of mothers with positive sputum.

Environment

We have found that the incidence of tuberculous infection is higher in children from homes in which there is a case of pulmonary tuberculosis with positive sputum. It may be that this increased tuberculization can be accounted for in part by the environmental conditions. It is difficult to classify home conditions in a really

satisfactory way, but an attempt has been made to divide homes into three groups—namely, " bad " homes, " fair " homes, and " good " homes. This was done after consideration of (*a*) total income, (*b*) locality, and (*c*) general hygienic conditions. In a series of 494 homes in which there was no tuberculous person living, 110 were classified as " bad," 154 as " fair," and 230 as " good." The incidence of tuberculous infection in each of these groups was practically the same, the figures being 30.9, 37.6, and 35 per cent. respectively. In 228 homes where there was a person suffering from tuberculosis, the corresponding figures were 86.4, 76.8, and 68.6 per cent. These figures would seem to show that where there is no known tuberculosis in the home, the incidence of tuberculous infection is much the same, whether the home conditions are " bad," " fair," or " good," while in the case of the tuberculous household there is a considerably lower percentage of tuberculous infection in the " good " home than in the " fair " home, and much more is this the case when comparing the " good " with the " bad " home.

Conclusions

1. The Mantoux test is more delicate than the Pirquet test. The Pirquet test is equivalent to 0.1 c.cm. of 1 in 10,000 tuberculin given intracutaneously.

2. The incidence of tuberculous infection in children increases gradually from infancy to puberty.

3. The incidence of tuberculous infection up to the age of 15 years is 43.1 per cent.—23.0 per cent. are infected between 0 and 5 years, 39.0 per cent. are infected between 5 and 10 years, 58.3 per cent. are infected between 10 and 15 years.

4. The incidence of tuberculous infection is slightly higher in girls than in boys.

5. The incidence of tuberculous infection in children between 0 and 15 is doubled when there is contact with open tuberculosis.

6. The incidence of tuberculous infection from birth to 5 years is five times greater when there is contact with open tuberculosis than when there is no contact with the disease.

7. The incidence of tuberculous infection in children of tuberculous fathers with positive sputum is slightly higher than in children whose mothers have positive sputum.

8. Our figures suggest that the incidence of tuberculous infection in contact children in " bad " homes is higher than in contact children in "good " homes.

THE NEED OF EDUCATION IN QUESTIONS OF SEX *

BY

THE REV. T. WENTWORTH PYM, D.S.O., M.A.

CANON RESIDENTIARY OF BRISTOL

It would be a mistake to suppose that education in sex matters refers solely to physiology. There is plenty of evidence that ignorance of the body may breed sex-mismanagement; but there is also evidence that physical knowledge, while, no doubt, protecting informed people from the worst physical consequences of sex-mismanagement, by no means ensures correctness of conduct. By sex-education I mean the physical, but also, the social, the moral, and the emotional (or what may be called the psychological) aspects. Again, while believing in the need of education in this more comprehensive sense, I do not believe that education alone, however complete in these ways, can be counted on to do more than point the way and ease the burden. As you would expect of me, I hold that as body must be directed by mind, so mind must be informed and empowered by God Himself. This recognition of man as what we clergy call a spiritual being does not, perhaps, concern doctors as a professional matter, but I should run the risk of being completely misunderstood if I omitted all reference to it. I put it now in the forefront because of its supreme importance; I do not propose to say more about it because it is my business to open a discussion on those other aspects of our subject which give common ground to us all.

The first of these to consider is the mind of the educator; and here we are faced with the difficulties which inevitably belong to a period of transition. The required instruction must often be given by those who have not completely escaped from the atmosphere of ignorance, negation, fear or disgust in which they themselves were brought up. When harm is alleged to result from education in sex we may suppose that it is nearly always due to the fact that the information is given in the wrong way. Wrong attitudes of mind in the educator may be briefly summarized: his own experience of life may lead him to over-emphasize dangers, sins, abnormalities; or he has escaped from the view that he is dealing with a dark and mysterious subject, but still keeps it in a water-tight compartment and deals with it in a highly specialized manner instead of as a universal part of life as a whole; or his approach is over-emotional, and he cannot speak of the physical side of sex in that matter-of-fact manner which we find and envy in those who profess the science of medicine. He is furtive where he means to be reverent, alarming when he means to be cautionary, and over-stimulating through his ardour for righteousness; or, worst of all, his own interest in the subject is morbid, obsessional.

The result of wrong attitudes in the educator must often be injurious to the boy or girl to be educated; the pupil is needlessly stimulated or frightened, and may, even after some instruction, regard sex-energy as a force to be suppressed rather than as a creative faculty to be directed aright and to be controlled for that end. Hence the need of emphasizing the importance of educating the educators. The Lambeth Conference indicated parents as the people directly responsible and the Church as the quarter to which parents should look for guidance and equipment. But it would be useless to ignore the fact that a majority of parents are incompetent for the task, and only a minority of clergy possess, at present, the knowledge required to provide the right guidance. During this transitional stage it may be necessary that certain people, men and women, chosen for the purpose, should be available as educators of educators, working to widen the area of competency.

Be that as it may I venture, as a father myself, to illustrate the part to be played by parents in very early stages. There is much to be said, which for lack of space must be here omitted, about the atmosphere of the home, the way in which father and mother treat each other, and

* Read in opening a discussion in the Section of Medical Sociology at the Annual Meeting of the British Medical Association, Eastbourne, 1931.

ogether treat the children; I omit too questions of general raining of children in the home; it should be obvious, or instance, that the spoilt child, the child who has everything he wants and never learns to "use the world and ot ab-use it," is likely, some day, to regard any control f sex-desire as absurd. I will pass at once to a particular oint which, while it seems to me of great importance, is learly one upon which the opinion of medical men and omen would be valuable if not decisive. I refer to proper nstruction in the physiology of the evacuation of waste naterials from the body. I urge the importance of this or two reasons. (a) The child's curiosity about and nterest in evacuation normally appears in consciousness efore interest in sex-matters. Thus a chance is presented f giving information about the general working arrangements of the body before any special sex-instruction comes; nd so the latter, when it becomes opportune, does not ppear to the child as an isolated and peculiar excursion nto bodily affairs; it fits into a field of information into which the child has already been led. From the very start sex is connected with and not divorced from ordinary life nd ordinary treatment of life. Elementary biology and botany may serve as a very useful preamble to sex-instruction, but science should surely figure in education at a very early stage and not appear first, or only, as the vehicle of instruction in sex. That would be to give to sex just that touch of peculiarity which is undesirable. But to play her part aright along these lines the mother needs double help; she must have correct information, and usually and rightly distrusts such information if it does not proceed from a medical source. But even if she has a cheap and trustworthy handbook, she often needs assistance in translating technical description into the language and idea agreeable to the child-mind. When the child asks "Where does my food go when I swallow it?" the answer should not contain the word "oesophagus"; it is possible to make the food's journey and use adventurous and interesting without so much as mentioning a "colon." But at present there is too wide a gulf between technical knowledge and language on the one hand and the needs of the parental educator on the other.

There is (b) a further reason why correct instruction about evacuation will render sex-instruction the easier. At present the uninstructed boy and girl are faced, even though unconsciously, with a truly disastrous confusion. When, in adolescence, they become physically aware of sex, the sensations occur in a locality of the body which is bound up, in their thoughts, with what is dirty, shameful, unworthy. Small wonder that father looked furtive and mother grew hot at any reference to procreation! It is all connected with dirt! This is at any rate one reason why the walls of public lavatories for men are so constantly the scene of lewd drawings and remarks. Against such a background in the mind of the child, to present sex as sacred or noble is often a herculean task; for it means not only teaching, but un-teaching—the most difficult educational performance.

I beg to submit for criticism an estimate of the correct background, collecting into one speech the fragments of teaching given at one time or another by parents or nurse:—"Good health depends more than anything else on our having clean insides to our bodies. Those parts of your body which help it to keep clean, by getting rid of waste stuff which is not wanted, do one of the most important duties for the body, and are to be honoured accordingly. Yes, I know you go to a separate place to get rid of this stuff; and you do so largely for the same sort of reason that you don't (if your house is large enough) brush your teeth or wash your hands at the table where the meal is laid. It is because what is got rid of is dirty or even poisonous; the parts of your body used to get rid of unwanted parts of food are very important, must be kept clean themselves and guarded from interference, like your eyes. Later on you will learn of an even more honourable place in life taken by that part of your body or by another very close to it."

The duties of parents towards young children do not end with the supply of a decent background for later instruction in the physiology of sex. An immense opportunity is presented by the questions asked by children. There are two things to be said about the matter, and one about the manner of the answers to be given. The question must be answered truthfully; that is the first thing. It is almost impossible to exaggerate the harm done by lie or evasion, especially where the offender is the child's parent. It is permissible to say "I don't know" or "You wouldn't understand if I told you now; ask me again a bit later on." If the question is asked in the presence of a visitor it is permissible to say "Mrs. X knows all about that, and I don't want to bore her; I'll tell you when we're alone." It is not permissible to say "Sh! Sh! You mustn't ask questions like that." The impression made on the visitor matters hardly at all; if she is of the kind to be shocked by truth, shocked let her be; for the impression made on the child may well be of life-long importance. There are very good reasons for giving a child all the possible information demanded; in the first place unsatisfied curiosity is a strong ally of sex-irregularities; in the second place the questions of a child have their own right to be answered; in the third place the questions of children about sex are not usually difficult to answer for anyone who has taken the trouble to acquire the information and to translate it into non-technical terms.

If the first rule about children's questions is to answer truthfully, the second is not to say more than is asked. An illustration will make this clear: The boy of 4 or 5 asks "Where was I before I was born?" The father replies "Mummy was keeping you warm and safe in her body." In 999 cases out of 1000 the enquirer is satisfied for the time being; his question is answered; the present need of his curiosity has been met, and the mood very quickly passes. But, unfortunately, while his mind is proceeding from the location of babies to a painter on a ladder at the house next door, father is conscientiously availing himself of the "heaven-sent opportunity"; he launches his set speech about bees and flowers or the marital customs of domestic animals. At best the child is bored; at worst his intelligence is over-stimulated on the subject and he carries away the impression, to which as an older boy he will return, that on this subject of birth and babies his father is heavy and unnatural. Why?

This brings us to the one essential rule about the manner of imparting information; this must be natural, ordinary, unstrained. The boy is playing bricks on the floor and asks why the milk is delivered in bottles; his father answers from the arm-chair without lowering the book which he is reading. Five minutes later the boy asks a sex question; the father must answer in the same manner as he replied previously; if he puts down the book and prepares for a conversational high-dive he introduces into the atmosphere a tension which will not escape the sensitiveness of most children. And so we return to the mind of the educator as the most important factor in sex-education.

I do not pretend that the subject of how to present sex to the child-mind is exhaustively laid out in the foregoing remarks; I have sought to dwell in some detail on points of importance which seem to be commonly disregarded. It is impossible to give even so much detail to all the different stages of sex-education. There are two stages in the whole concern which are, I believe, of greate

moment than any others; one is that which has already occupied our attention. That view of its importance is thus described by the Bishops in the 12th Resolution of the recent Lambeth Conference: "It is important that before the child's emotional reaction to sex is awakened definite information should be given in an atmosphere of simplicity and beauty." My claim would be that those words justify the emphasis given in this paper to the mind of the educator and to the treatment of quite young children.

The other vital point seems to me to be preparation for marriage, and to that we shall come. But in between lies that vast tract of territory which comprises later childhood, adolescence, courtship, and what may be called "involuntary celibacy." Before an audience such as this I presume that it is unnecessary to spend time in arguing the need of right sex-instruction for these stages; I therefore merely single out a few items for special emphasis. For instance, I do not believe that the instruction of adolescents should be done in groups, whether in school or Confirmation Class. The botanical or other general scientific background—the positive teaching which links the subject healthily to creative activity in life as a whole; yes; but when one comes to the specific application to the sex-development of boy or girl, and to the warnings and advice required, personal instruction is necessary. It may not be always possible; I know the difficulties, but if they can be overcome so much the better. For the physical and emotional development of different boys and different girls varies very greatly; what in the group-teaching may be suited to one boy is too puerile for another boy and too advanced for a third; besides, many groups will contain the joker, the decadent, or loose liver who may afterwards ridicule or otherwise degrade and misuse the teaching which has been given.

At this juncture I have in mind the minister of religion, the scoutmaster, the school-teacher, the club-leader and others who are connected with adolescents, rather than the parent. For in so many cases the home is unable, or if able unwilling to perform the duty. Is there any general method which, though it may admit of many exceptions, is to be recommended? I believe that there is, and it is most important that such a recommendation should be in terms of the ordinary man or woman; it may assume good sense and goodwill, but it will be of little practical value if it assumes expert omniscience. Hence literature, perhaps of two kinds, is required; certainly a choice of booklets for the young person, and perhaps a booklet or book of a more advanced type for the preparation of the educator. The latter will select the booklet which he judges to be the best suited to the age and development of the particular boy. He will give the booklet to the boy to read; if it can be avoided the literature should not be lent to be taken away, but read on the spot and returned. If so the educator must strive to be unhurried; he will not fuss around or cause the boy to feel "under observation"; he will, for example, turn to his table and get on with his own occupations. When the boy has comfortably finished, a conversation will start from the matter which has just been read; a suitable opening remark often is, "Well, how much of that did you know already?"

It is again necessary to stress the importance of the educator's own mental condition during such an interview. He must not be tense or strained; he may be bound to talk about emotional matters, but he must not talk about them emotionally. If he cannot conform to this principle he is not a suitable person to give the instruction. Where the words "boy" and "man" have here been used the words "girl" and "woman" may also be read. There are very few exceptions to the rule that a man (other than a doctor, and then only in special cases) should never instruct an adolescent girl in the physiology of sex. If clergy were to tell me that they do this successfully with girl confirmation candidates, I could only suppose that they omitted essential parts of the information required. For a man to include it all, in talking to an adolescent girl, would be to run the grave risk of stimulating her in the wrong way; at best the normal girl would be consumed with shyness. Besides which the right woman can obviously perform this duty better than a man. One of the first duties of the clergy in sex-education is to secure the services of the best woman available, to whom the adolescent girl may be passed on.

The assumption which lies behind all this is that the required literature is available. This is not so. There is some good literature, but it is not widely known. We should notice that here are really two quite separate points: (1) the existence of the literature, (2) its availability. The Lambeth Conference precisely defined this double difficulty when it stressed the need "to review the available literature and to take steps for its improvement and its circulation."

Now there are three objections, one or more of which apply to a great deal of the literature in use for sex-education: (1) The fear-motive is too prominent. I do not say that this motive has not its due place; certainly it has. But any pamphlet which starts from it or harps on it, any pamphlet which deals too exclusively with sex-error and its consequences, and treats sex as a dangerous rather than as a creative faculty, stands self-condemned for ordinary use. (2) The pamphlets tend to become out of date. The divergences may not be very serious, but in view of the enormous strides made in recent years by medical researchers (not forgetting psychologists) in this subject, we clergy need protection from the suspicion in our minds that we are handing out physiological or psychological information which would be contradicted by the scientist. (3) Many of the existing pamphlets quote as authorities medical names which altogether lose their impressiveness on investigation. Disguise is best achieved here by exaggeration, so I will exaggerate. In a pamphlet I read that a very distinguished man of medicine has stated that "For the normal man or woman continence need never be injurious to health." I am impressed. But, not knowing him by name, I investigate. The gaps in my knowledge of medical history are revealed, for I find that this man was once at the head of his profession, having been Court physician to one of the Hanoverian kings. This discovery sobers me considerably, and I ask myself, "Is this impressive name retained in this pamphlet, because no physician of like eminence could be persuaded in more modern times to utter in favour of continence?"

In answer to me on this third point it may be said that distinguished medical men and women have in recent years corroborated the opinion just quoted. But here comes difficulty about publicity or circulation. "The statement was published by some society; but by what society? and what was it called? How can I get hold of it? My bookseller doesn't know; nor does my Rural Dean." But even if I can discover it there remains a certain objection to the authority of a document signed in their individual capacity by people, however eminent. It carries the weight of those people's reputation, but can be and is contradicted by other members of their profession; for doctors, and not clergy alone, have been known to contradict each other's opinions.

It would scarcely be appropriate that this meeting should discuss how the Bishops of the Anglican Communion should translate into action the desire about literature expressed in the 12th Resolution of the Lambeth Conference. But let us make the hopeful assumption that soon the suggested review of literature and of its availability

nade, and that some body of people is commissioned to the gaps. I am sure that in the future, as in the past, ding medical men and women will help the Church to fill existing gaps in the best possible way. But I suggest it more is required. We need some seal upon any such blication, to assure those who use it that the scientific ormation contained in it is substantially correct. Such imprimatur could easily be so worded as to make it ar that reference was being made only to the scientific tements of fact, and not necessarily to the use to which ey were put. The literature so certified could be recom-nded the more confidently by Bishops to their clergy d by clergy to their people. Medical societies are a eater mystery to the laity than ever can be clerical chap-rs or assemblies to the doctor; so I do not profess to ow exactly by what body or in what way this suggestion uld be carried out. But I hope that a Section of the itish Medical Association is not an improper place at hich to ventilate the idea. Could not some authoritative edical body, with a reasonable claim to speak for a ajority of the profession, issue, through a Committee ppointed by its Council, some such certificate for sex-erature, the medical part of which was approved? The fer of such help to the Archbishops would be a graceful, nd I should guess, valued response to the appeal of the ambeth Conference for co-operation between our two pro-ssions; it is true that that appeal was not in the context sex, but no subject could benefit more greatly by an crease of such co-operation.

It remains to comment in some detail upon part of that ivision of sex-education which is becoming known as 'preparation for marriage." The selection of this division f the subject has been made for two reasons; in the first lace it is a form of education which until quite recently as been ignored; in the second it appears, at least to he writer of this paper, and not to him alone, the most mportant section of sex-education as a whole because o much hinges on it. We have had occasion to note hat the present is a period of transition; we recog-nize the importance of early teaching for children, yet re bound to admit that only a minority of married couples have the knowledge and willingness to perform this duty. At some later stage the competent educator is handicapped by the fact that he is late in the field; there is so much to unteach; so much harm has already been done. Thus there is a sort of vicious circle; every phase is important, yet in each there is liable to be a handicap. I believe the most important point at which to break through is marriage. For proper preparation for that may not only increase the number of happy marriages, but it should be the door through which may be secured right educa-tion for the children of those marriages. Thus it may herald the slow dawn of a new era. I would say nothing to discourage the efforts of those who are addressing them-selves to other phases of the general problem of sex-educa-tion; a general effort is needed all along the line, but in that effort marriage is a crucial point.

The Bishops have not yet amplified or defined their Lambeth appeal for "some further preparation for those members of the Church who are about to marry," but it may be safely assumed that they meant very much more than physiological instruction. There is definitely religious instruction, practical common-sense advice of the give and take, the mutual adjustments required in the married state, the law of the Church and so forth. There is much to be said about the conduct and influence of the home, about the technique of self-control in the most intimate relationships of married life. I do not wish even to seem to reckon any of these of small account, through omitting them now, nor to imply that doctors, whether as men and women, or in their professional capacity, have no voice in these matters and no oppor-tunity and duty of influence. But in order to make the best practical use of the time remaining to me I will con-fine my remarks to that part of the subject which obviously commands medical interest.

The respect in which the contracting parties to a marriage greatly need education is in their mutual ignor-ance, man of woman and woman of man. The cynic may retort that on the man's side at least this might be remedied by premarital recourse to prostitution. Actually the reverse is true; the professional or promiscuous woman does not reflect the physical and emotional reactions of a decent woman, and the man who treats his wife in inter-course as he has treated other women before may lay the house of married love in ruins. But the difficulties of the situation are not confined to the man of previous experience of some kind. Man is, for example, ignorant of woman in that he does not know that her inclination towards intercourse is normally much more gradual than his, and that when intercourse has begun her progress to-wards complete experience, physical and emotional, tends to be slower than his own. Whether or not, at all, such ignorance is to be found within the medical profession, there is, I submit, enough evidence to support the state-ment that such matters go beyond the sheer physiological instruction received by the average medical student. A mechanic in a motor-works knows the different parts of a car; he is constantly manipulating them; he can teach another man their position and functions. But this know-ledge does not render him completely competent to drive a car, still less to teach someone else to drive it. On the other hand the car may be driven extremely well by someone who has very little technical knowledge of the insides of the car.

Now herein lies our great difficulty in what may be called the physiological part of preparation for marriage. It is a kind of No Man's Land. Your profession may claim it as "medical." You may say "Send your pro-spective bridegroom to a doctor." But can you accom-pany that advice with any assurance that the average local general practitioner is competent to deal with the situation? If you cannot yet give that assurance will you help the married clergy to give the right help to men, and selected married women to give the right advice to women about to marry? I will not delay you now with any consideration of the organization required in the ministry of the Church to meet the need which I am outlining; that must be and can be thought out and provided. I will only add a few other illustrations of the existing need.

There is a very common and injurious assumption that consummation must take place the first night of married life or at the very first opportunity afterwards; to this is attached the rumour that the experience must be painful or at least unpleasant for the woman. Neither man nor woman is equipped with any knowledge of how to deal with this situation; the man is anxious to get the business over; has not his wife just promised to "obey"? Nervous roughness on his part—in some classes of life deliberately reinforced by alcohol—may produce disgust in her. What was meant to be sacramental, the outward expression of a love which combined body, mind, and spirit in man and woman, becomes degraded into the satisfaction of the body of one alone. For the union is not merely physical and it cannot so be labelled; it is mental, emotional, moral, spiritual—at least, in true marriage, it should be so.

The following may be listed as some of the causes of divorce, and of many more unhappy marriages, due to an ignorance neither invincible nor unavoidable, an ignor-ance which, by the efforts of Church and Medicine, must be removed: Nervous impotence on the man's part; lack of response on the woman's; the folly of the

deliberate avoidance of any children; indulgence which is one-sided; over-indulgence and lack of any system of control; to such major causes might be attached many important, though in a sense, minor matters. I do not mean that these difficulties and failures should be treated negatively, as things against which cautions should be given; they are to be avoided by quite simple positive information before marriage. It may be urged, of course, especially against such preparation for marriage, but also against the whole idea of the need of education in questions of sex, that any such education is highly artificial; that sex is natural in man and woman, and should function spontaneously. It is perhaps hardly necessary to take such an argument very seriously before a medical audience. The history of civilization at its best is the history of an increasing understanding and control of natural forces that they be directed towards the noblest ends; from that progress we cannot now step back. The choice is quite clear; either back to the jungle from which long ages ago we emerged; or on to the City of God.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

CALCIUM LEVULINATE FOR INTRAVENOUS AND SUBCUTANEOUS INJECTION*

In recent years it has become obvious that in certain cases calcium must be administered more rapidly and efficiently than is possible by the oral route. Thus, in the case of tetany following thyroid operations, in the vomiting of intestinal obstruction, and also in some recently discussed conditions such as osteitis fibrosa cystica and coeliac rickets, the tetany has been relieved by the intravenous and subcutaneous administration of calcium salts. Again, the use of calcium salts intravenously has been recommended for pre-operative treatment in various surgical conditions, especially in jaundiced patients.

The use of the simple inorganic salts (for example, calcium chloride) for intravenous injection is undesirable, as ulceration usually follows if extravasation occurs. For this reason various organic salts of calcium have been tried, but these have all suffered from the disadvantage of their relative insolubility. With some, however, the desired concentration can be attained by using a supersaturated solution, as is done, for example, with calcium gluconate; but since this method is rather limited, it was felt that a more soluble calcium salt suitable for injection should be sought. It was found that the calcium salt of levulinic acid possesses the desired properties. This salt, which has the composition expressed by the formula $(CH_3.CO.CH_2.CH_2.CO_2)_2Ca.2H_2O$, contains 13.1 per cent. of calcium. It is very soluble in water, stable 25 per cent. solutions being obtainable with ease. Stronger solutions are syrupy. The solutions are stable at 100° C. The reaction of a 10 per cent. solution lies between *p*H 7 and *p*H 8.

In case the levulinate ion should prove to be strongly toxic, the effect on the blood pressure of an anaesthetized cat of a solution of calcium levulinate was compared with that of a supersaturated calcium gluconate solution of the same calcium content. The depressor effects of the two solutions were approximately the same. A dose of 33 mg. of calcium per kg. as 25 per cent. calcium levulinate was also given intravenously to each of three rabbits without any mishap.

The effect of injecting 20 c.cm. of 10 per cent. calcium levulinate intravenously into a normal person was investigated. No unpleasant result ensued. A similar solution was given intravenously in four cases of tetany, and in the pre-operative treatment of five jaundiced patients. There were no reactions whatsoever; and, further, ulceration does not seem to follow extravasation, for in one case where the latter accidentally occurred no sloughing resulted, although there was a fairly severe haematoma. We would point out that owing to its great solubility calcium levulinate is particularly suitable for subcutaneous injection.

We have to thank the Crookes Laboratories for preparing for us the pure calcium levulinate referred to above.

CAESAREAN TWINS

I wish to place on record the following case of Caesarean twins on account of the extreme physical deformity of the mother, her ante-natal care, her rapid post-operative convalescence, and the extremely healthy condition of her children.

Mrs. X was born in 1897, and at the age of 4 was treated in Edinburgh for "curvature" of the spine. For three years she was kept in bed, and occasionally in plasters, till the hump became established and the pain from movement less acute. Her deformity became permanent in time. She first consulted me in August, 1925, on account of severe pain in her spine. I then made the following entry on her case sheet. "Marked kyphosis and scoliosis, large permanent hump on right side, pain on left side, due to pleurisy, enlarged glands in the right iliac fossa, and enlarged septic tonsils." She was treated medically, with slight improvement in her general condition, but she always remained a chronic suffering invalid. A spinal support was ordered for her, and she was instructed to wear it during the daytime only when she was on her feet. In March, 1928, I enucleated her tonsils under a general anaesthetic. Her health subsequently improved to a great extent, and she became pregnant in spite of the fact that she was still a virgo intacta, there having been on no occasion any penetration during sexual intercourse. Even digital examination was impossible. She was admitted to Nell Lane Auxiliary Hospital and *x*-rayed there. The pelvis was found to be flat, the outlet was very narrowed, and the promontory was bulging forward. The uterus was lying high up, and the cervix could hardly be touched by the finger. It was decided not to interfere with her condition, and she was allowed to carry on to full term.

She had no morning sickness, no albuminuria, and her chief complaint was backache. As there was no space in the right hypochondrium, where the ribs rested on the iliac crest, the uterine body at first occupied the left half of the abdominal cavity, later it became anteverted and almost fell out of the abdomen. From the fifth month onwards the patient lay in bed day and night; her uterus was placed on special pillows beside her. There was complete atony of the muscles of the abdominal wall, and special care had to be taken to carry the uterus when the patient left the bed.

On November 25th, 1928, when she was 8½ months pregnant, labour pains started at 4 p.m. I was sent for at 11 p.m., and at 1 a.m. I performed Caesarean section at Nell Lane Hospital and delivered her of twins. There was no difficulty in removing the two placentae, which were joined. There was no undue haemorrhage, the contraction of the uterine muscle being remarkably good in spite of the distension. She made an uninterrupted recovery, and was discharged from the hospital in three weeks' time. The babies weighed 3 lb. 10 oz. and 3 lb. 12 oz., which is very remarkable in view of the fact that the mother weighed only 5 st. before she became pregnant, and her height was 4 ft. 5 in.

To-day the children are remarkably healthy. They weigh 1 st. 13 lb. and 1 st. 11 lb., and have suffered from no illness except a mild attack of bronchitis. They have been brought up on a patent food.

Reports of Societies

EVOLUTIONARY TENDENCIES IN THE JAWS

At an address to the International Orthodontic Congress at the Savoy Hotel, London, on July 20th, Professor G. ELLIOT SMITH discussed evolutionary tendencies in the jaws and teeth.

He said that in seeking for an explanation of the strange vicissitudes to which the teeth were liable in the course of their development in man, it was important not to lose sight of the factors involved in the making of the human face and in providing it with new functions in addition to those it performed in other living creatures. For the changes which affected the jaws and teeth in the evolution of man were in large measure due to the growth of the brain and the enhanced significance of the face which the higher powers of visual discrimination and understanding conferred upon it. It became not only the most distinctive label of individual men and women, whereby their fellows could recognize them, but also the chief instrument for expressing the feelings and thoughts in a way that played so vital a part in social intercourse and in enabling human beings to express their own personalities and influence the behaviour of others.

Profound changes were effected in the face in man's remote ancestors during the process of acquiring the higher powers of vision, which were made possible by changes in the position of the eyes, the reduction and transformation of the snout, and what amounted to a profound reconstruction of the jaws and consequential changes in the number, form, and sequence of eruption of the teeth. Moreover, the growth of the larger brain and the cultivation of its complicated functions called for much more time than was required for the development of other creatures, and during the years occupied in those processes the eruption of the teeth was delayed. Most of the problems which were responsible for the creation of the orthodontic profession arose out of the circumstances created by these delays in the growth of the jaw while the brain was growing. If aesthetic considerations and men's interest in faces played some part in creating the demand for orthodontia, the growth of the brain was chiefly responsible for disturbing the orderly process of uniform growth of the jaws from which the dental troubles arose. Man had inherited from his immediate ancestors the same number, type, and order of development of his teeth. Even if nothing more of fossil apes and men had been recovered than their teeth, it would still have been possible to establish so complete a series of links as to bridge the gap between the living apes and men by following their respective lines of divergent ancestry back step by step to a common parent akin to the fossil ape such as *Dryopithecus*, which lived in the Indian Sivaliks in the Miocene period. Quite apart from all the other corroborative evidence, the morphology of the teeth, as Professor William K. Gregory had so clearly elucidated, and the structure of their enamel, as Mr. Thornton Carter had shown, were enough to establish the reality of man's simian ancestry.

The chin was the peculiar distinction of modern man. In the extinct members of the human family the lack of chin development became more pronounced as one successively compared with *Homo sapiens* men of the Neanderthal and of the Heidelberg species, until in Piltdown Man and Peking Man the deficiency became so pronounced that some anthropologists still refused to admit that they were human. It was not only the form and structure of the teeth and jaws of these primitive men, however, that were increasingly ape-like, but also the order of their eruption. In the human child there was a delay of four years after the milk teeth were erupted before the permanent teeth began to be "cut," and another ten or fifteen years might be occupied in completing the permanent dental equipment. In the apes the process of eruption of the second teeth followed more closely on that of the first teeth, and the second permanent molar erupted before the deciduous molars were replaced by the premolars. In the children of Neanderthal Man the surprising fact was now revealed, as Dr. Magnus Degerbøl of Copenhagen had recently pointed out, that the simian type of sequence was still retained in the eruption of his teeth. There were reasons for the inference that Neanderthal Man's defective chin development might be associated with this fact—that the precocious "cutting" of his teeth permitted the tooth-bearing part of the jaw more nearly to keep pace with the growth of the rest of the jaw. Modern man probably developed a chin because the growth of the tooth-bearing part was restrained by the long delay in the eruption of his teeth. There had been much speculation as to why this should be so, especially in recent writings of the late Professor Bolk, Dr. Degerbøl, and Professor Mijsberg. Yet it was strange that none of them had referred to the fact (so strikingly emphasized by Professor Elliot Smith's colleague Dr. H. A. Harris in the *Lancet* of March 28th, 1931, and elsewhere) that the human child until the seventh year, during the pause in his dental development, was growing a phenomenally large brain and for another fifteen years or so, and that while relatively sluggish in his dental affairs, he was occupied in learning how to put his complicated cerebral instrument to the biological uses which were vitally essential for human existence. The delay in tooth and jaw development was undoubtedly due to these momentous events. The salient chin was a manifestation of the great events which conferred mind upon its predecessor—it was an index of "mental" development in the psychological as well as the anatomical sense of that term.

Professor Elliot Smith, in conclusion, said that the wider vision of the evolution of the face enabled many false claims repeatedly being made about human tendencies to be viewed in truer perspective. The reduction in size or absence of the third molar was often claimed as a sign that man was destined to lose that tooth in the near future. In Peking Man, supposed by some palaeontologists to have lived as many as a million years ago, the third molar was smaller than the others. The same condition was not uncommon in apes and monkeys. It was, in fact, a tendency which the whole order of primates inherited, but there was no just reason for assuming that either the third molar or the second incisor was about to disappear in man in the near future. Nor did there seem to be any justification for the belief that dental troubles, such as crowding and displacement of teeth and the consequential difficulties, were due to evolutionary changes that were now active. There was no evidence that, apart from the results of racial mixture, any detectable changes were taking place in the jaws and teeth. The same irregularities and deficiencies in the teeth were occurring fifty centuries ago. Contrasts in the form and proportions of the jaws were just as marked. Civilization could not be held responsible for these things except in so far that it promoted a freer intercourse among people of different antecedents and so conduced to racial admixture and the conflicting tendencies in jaw and tooth development. Evolution worked with exceeding slowness, and there did not seem to be any certain evidence that any effects that could be attributed to recent evolution had yet been detected in modern man's jaws and teeth. In the process of admixture of peoples of different strains it must happen that, as the rigid and unalterable forms of the enamel caps of the teeth had to be lodged in the more plastic bone, disharmonies in the inherited proportions were certain to emerge, even if the jaw was endowed with wide powers of adaptation to exceptional conditions.

Reviews

X-RAY EXAMINATION OF THE RESPIRATORY TRACT

Professor ÉMILE SERGENT'S book on the Radiological Examination of the Respiratory Apparatus[1] is not so much a theoretical treatise on the subject as a practical description of the various appearances seen both on the film and on the screen examination. He has been ably assisted by Drs. BORDET, DURAND, and COUVREUX, the last dealing with the technical details of the subject. The photographs, which constitute the material of the book, are taken from a number of radiograms and pathological specimens collected during the course of ten years' clinical work. The authors consider the subject from the clinical point of view, always comparing the radiological appearances with pathological findings. They have attached to the various images an interpretation which would agree with the signs and symptoms recorded by other methods of examination, and which are controlled by the findings at necropsy. Indeed, as Professor Sergent has expressed it, "a radiological examination is an autopsy of the living."

One of the greatest difficulties that beset an author of a work of this kind is that of obtaining a faithful reproduction of the details furnished by a good film. It is true that the respiratory apparatus lends itself better than any other system to a radiological examination. It reveals itself by the normal contrast of light and shadow, yet a good technique is essential to show the fine details of the bronchial and vascular arborescences. It is these that are difficult to reproduce in a book. They disappear if the reproduction is too much reduced. In consequence, the authors have used a folio page to maintain the dimension of the film, and have reproduced several enlargements of particular zones to render the fine details more apparent. The photographs are reproduced particularly well on a thick heavy paper, which renders the division of the work into two volumes ("for foreigners") a boon. The book is divided into three parts: the first describes the technique; the second the normal findings, accessory methods of examination, such as lipiodol, and the different types of opacity and translucency; while the third details the radiological appearances observed in the various affections of the respiratory apparatus. The volume is beautifully illustrated; indeed, there are no fewer than 639 plates, mostly radiograms. Each is described clearly and concisely, but otherwise the text, though good, is of secondary importance. The inclusion of photographs of pathological specimens beside radiograms of similar conditions is a very instructive feature. This is an excellent work—a credit to authors and publishers alike. It is more than an atlas, being full of practical details, and is interesting from start to finish.

THE SURGERY OF INJURIES

Surgery has been more subdivided and specialized in the United States than in Europe, so that the invention of the terms "traumatotherapy" and "traumopathy" has found acceptance there, and Dr. JOHN J MOORHEAD is director of the department of traumatic surgery in the New York Post-Graduate Medical School. In the preface to his book, *Traumatotherapy: The Treatment of the Injured*,[2] Dr. Moorhead makes no excuse for his specialty, having satisfied himself by the reception of his previous work, *Traumatic Surgery* (1917), that the superficial treatment of the subject is acceptable to his colleagues. Seeing that the technique of treatment is of supreme importance in this branch, he has attempted in this volume to detail the actual management of all the usual and most of the unusual, effects of trauma. In this way the treatment of the usual effects of trauma has become almost standardized since the experiences of the great war and the rising flood of industrial and transport accidents, but in practice it is to be feared that the technical skill and ability necessary for the successful application of the theory is not so widespread as could be desired. Therefore a work which lays down the principles of treatment of injuries clearly, and teaches the details of their application, is to be commended.

Some idea of the scope of the work may be got from a perusal of the chapter headings. These are:

I, Contusions; II, Wounds; III, Dislocations; IV, Fractures; V, Closed cavities trauma; VI, The traumatic neuroses; VII, Injury by electricity, *x* ray, radium, ultra-violet light; VIII, Amputations; IX, Bone plastics; X, Soft tissue plastics; XI, Osteoma—exostosis—myositis ossificans, Malignant Trauma and malignancy; XIII, Post-traumatic deformities and disabilities; XIV, First-aid treatment—standardized procedures; XV, Antiseptics—drugs—dressings; XVI, Splints and apparatus; XVII, Anaesthesia; XVIII, Restoration of function; XIX, Treatment of injuries in the young; XX, Treatment of injuries in the aged; XXI, Treatment of old injuries; XXII, Manipulation in certain joint injuries; XXIII, Combined traumatotherapy and after-care; XXIV, Medico-legal and allied aspects; XXV, The prone pressure method of artificial respiration; XXVI, The Carrel-Dakin technic.

Having in mind the fact that this is a book on treatment and not on pathology, we think that the author has represented his subject-matter as fully and as clearly as is possible in 574 pages and 625 illustrations, and that its readers should gain much valuable knowledge, always remembering that technique cannot be fully acquired by reading books, but that actual practice is necessary to complete the instruction given by lecture or textbook.

A SHORT HISTORY OF BIOLOGY

Although there doubtless exists, among educated people generally, a wide interest in the subject of biology, it is probably equally true to say that there is great ignorance of the scope of the science and of its present position. A concise account, in non-technical language, is therefore likely to prove useful, provided it includes a comprehensible exposition of the science as it stands to-day, such as may be found in Dr. CHARLES SINGER'S *Short History of Biology*.[3] Several excellent histories of biology could be mentioned the value of which, to the general reader at least, is heavily discounted because they stop at some convenient point in the history which dispenses with the task of exhibiting the present position of the science. The latter, however, is what the general reader wishes to understand. He has been fully informed on certain well-ascertained facts—that science originated with the Greeks, declined under the Romans, revived in the thirteenth century, and made rapid progress on the introduction of the inductive method, with its classifications, systems and geographical and geological explorations. His difficulties arise with the present; for example, he has accepted the Darwinian theory of evolution, but experiences some confusion of ideas when told that Darwin's reasoning on natural selection is based on a series of fallacies. Nor are his difficulties diminished by a tendency exhibited by some authors, to blurr the distinction between theory and ascertained fact—to exhibit

[2] *Traumatotherapy: The Treatment of the Injured*. By John J Moorhead, B.Sc., M.D., F.A.C.S. (D.S.M.) Philadelphia and London: W. B. Saunders Company. 1931. (Pp. 574; 625 figures. 32s. 6d. net.)

[3] *A Short History of Biology*. By Charles Singer. Oxford: At the Clarendon Press; London: Milford, Oxford University Press. 1931. (Pp. xxxv + 572; 194 figures. 18s. net.)

inclination to leave open questions open The shifting gmas are confusing to the general reader, who is not vays able to distinguish dogma from legitimate pothesis

The virtue of Dr Singer's book lies in his regarding e present position of biology as embodying a number of solved problems He mentions the main themes which e engaging the attention of biologists, and traces, his rically, the manner in which they have emerged—mely, the evolutionary history of living forms, the gnificance of the cell doctrine, the nature of vital tivity, the interrelation of the various organic functons, the origin of life, and the mechanisms of sex and redity In the discussion of these problems a comprenension of their bearing is greatly assisted by many dicious comments on the part of the author On the ew adopted by Dr Singer, biology may aptly be com ared to a number of converging streams, which have ready been traced for a certain distance from their ource, but the lower reaches of which are unknown and main to be explored The subject is one, therefore, in hich there is much room for the exercise of the open ind and the avoidance of dogmatic assertion

EUGENIC STERILIZATION

n the *Journal* of December 7th, 1929 (p 1069), we eviewed a book, entitled *Sterilization for Human Betterent*, by E S Gosney and Paul Popenoe Both these uthors are prominently connected with the Human letterment Foundation of Pasadena, California , indeed, he former is its founder, and has been alone responsible or its finances on a large scale, while the latter may be lescribed as its pamphleteer and propagandist The book eferred to was a summary of the results of 6,000 steriliza ion operations in California during the twenty years prior o 1929, and there has now been issued, under the uspices of the Foundation, an irregular volume of pamphlets, entitled *Collected Papers on Eugenic Steriliza ion in California* [1] These pamphlets appear to have been ublished between the years 1927 and 1930 inclusive , all ut one or two are by Dr Popenoe, and they deal with he same 6,000 cases as the book already reviewed, ogether with a relatively small number of additional ases The volume will be convenient for those who like o have these papers to refer to, but its value is not reat The statements made about the book—that it as well informed within its compass and relatively temerate in statement—are true about the pamphlets for he most part , but unfortunately neither of the volumes s characterized by a really scientific outlook The point of view is biased throughout, arguments are twisted to suit he immediate needs of the writer regardless of consistency, nd sweeping conclusions are repeatedly drawn from meagre statistics or a very small number of cases The contention is that all " persons in the community whose children would be a liability rather than an asset to future generations because of their inherited natures " should be sterilized, and that California offers an example to the world in that a large proportion of those entering or leaving institutions for the insane or the mentally deficient are subjected to sterilization, and that there are a large number of sterilization operations voluntarily submitted to outside these institutions The " results " of all this are discovered in the various pamphlets to be in accordance with the wishes of the writer The material for the separate papers is usually inadequate and the argument often puerile Good behaviour *although* sterilized, and good behaviour *because* sterilized, are frequently used and stipulated just as Dr Popenoe thinks fit It is admitted that a large number of the patients will have to remain in institutions all their lives, and that a very large proportion of the others really behave themselves when placed in the community under some supervision as well as the rest of the population Nevertheless sterilization is claimed as the right procedure for all A remarkable paper is that entitled " The number of persons needing sterilization," for it illustrates alike the disregard of the need for accurate figures, the vague guessing at percentages, the loose statements about human heredity in general, and the tendency to widen to an absurd degree the categories of those to whom sterilization should be applied The curious, but evidently welcome, conclusion is reached that, even if these calculations are inaccurate, and even though at first it may not be advisable to sterilize all of those included, there will still remain enough people requiring operation to keep the surgeons and hospitals of the United States continuously busy. The whole question of sterilization, its proper sphere, its limitations, and the conditions under which it might be legalized, is now being seriously considered in this country It is to be feared that the experiences of California, as set out by Dr Popenoe and the Human Betterment Foundation, will not be found of much value or help in this connexion

A short pamphlet entitled *Psychiatric Indications for Sterilization*,[2] by Dr ERNST RÜDIN—an abridged translation from the German—is on a different plane It is a temperate and scientific statement, maintaining that, in a certain limited number of insanities and diseases of the nervous system, the advisability of sterilization has been proved Everyone will not accept even this conclusion as settled, but all will agree with the main purpose of the pamphlet, which is to urge the need for immediate and active research in hereditary prognosis The author says " To judge the case *post hoc* is easy enough, but we ought to be able to give sound advice before the appearance of those unhappy individuals whose birth we aim at preventing ' , and, again, " careful and authoritative pronouncements in regard to the laws of hereditary transmission are imperatively required Vague general statements as to suitable cases I hold to be of very little use "

HUMAN EMBRYOLOGY

A Textbook of Human Embryology,[3] by Professor SIMKINS of Tennessee Medical School, affords further evidence of the importance attached in the schools of America, not merely to the subject of embryology, but also to the manner in which it is presented Professor Simkins has had the advantage of being able to consult the works of others, such as those of Arey, Dodds, Kellicot, Jordan, and Kindred, to mention a few recent publications, and also to benefit by the use of their illustrations—no small benefit in a subject so dependent for its adequate treatment on the art of the draughtsman The figures of wax plate reconstruction models are particularly successful, and of these Professor Simkins avails himself unstintingly The book is on the whole clearly written, although, as in the account of the development of the visceral cavities, the author relies a little too much on the illustrations for his meaning , further, he has made every effort to bring the reader abreast of the latest knowledge, a desire which at times leads him into details which, as, for example, in the account of the segmental arteries and their anastomoses, tend to obscure the main outlines The subject is at the present day, we are

[1] *Collected Papers on Eugenic Sterilization in California*. With an Introduction by Guy Irving Burch. Pasadena, California: The Human Betterment Foundation. 1930.

[2] *Psychiatric Indications for Sterilization*. By Dr Ernst Rüdin. Abridged translation. London: Eugenics Society, 1931. (Pp 19. 6d.)

[3] *Textbook of Human Embryology*. By C. Cleveland Simkins, Ph.D. Philadelphia: F. A. Davis Company. 1931. (Pp. xiv + 469, illustrated. 4.50 dollars net.)

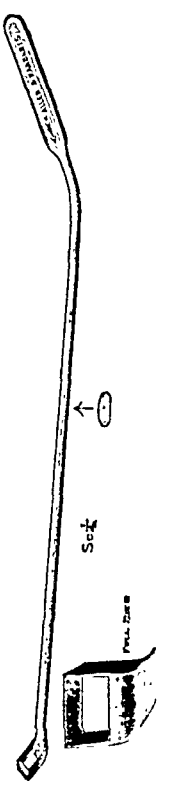
inclined to think, from the student's point of view sorely in need of judicious abridgement and of concentration on the main facts and principles. A very welcome feature of the book is the attention paid to "anomalies," for these are not only of great practical importance, but often serve to drive home certain fundamental facts in an interesting and impressive way. The book can be warmly recommended to the student for its accuracy and comprehensiveness, but we hope that in any future edition the proof-reader will be less at fault and avoid the complications which may arise from such bibliographical references as "Keeth, Embry., Morph and Arnold."

NOTES ON BOOKS

At the King Edward Medical College, Lahore, a post of *lecturer in anaesthetics* has lately been created, and the first incumbent of it is Dr. K. E. MADAN, who has promptly produced a textbook of *Elementary and Advanced Anaesthesia*[1]; primarily, we may suppose, for the use of his own students, but also, as he states himself, for practitioners of all types, including post-graduates. It is very possible that Dr. Madan is an expert anaesthetist with a firm grasp of the principles and practice of his specialty, but he has certainly not succeeded in expounding them in print. The impression left by the book is that it might have been produced by someone with an encyclopaedic knowledge of the literature of the subject, but with limited practical experience of the operating theatre. It may well be that this impression is not a correct one, and that it is due to Dr. Madan's inexperience in authorship; but it spoils the value of the book as a guide for the student and the practitioner. To give one very brief instance, the chapter on the choice of anaesthetics (quite one of the most important in any textbook on this subject) contains the following pronouncement, which is not qualified in any way, or modified by its context: "Chloroform is always indicated in all respiratory troubles—for example, of the larynx, trachea, bronchi, lungs, and pleura." We feel sure that Dr. Madan never meant this sweeping assertion to be accepted as literally true; but he has committed himself to it so categorically that his students must think he did mean it.

We have received the first issue, published in June, of the *Proceedings* of the Scientific Committee for the Investigation of Circulatory Disorders, whose headquarters are the William G. Kerckhoff Institute at Bad Nauheim, founded in 1929 by Mrs. Louise E. Kerckhoff in memory of her husband, and opened on April 12th. The issue contains the address delivered at the opening ceremony by Dr. Hamel, president of the German Ministry of Health, followed by a lecture by Professor Franz M. Groedel, director of the institute for circulatory disorders, and an account of the first meeting of the committee.

In *The Danger Signs of Disease*,[2] by "A Scotch Doctor," will be found a number of useful hints, warnings, and reflections on the subject of health and disease which may be of value to the observant and discriminating layman. The author says that his "main purpose is to enable people to appreciate whether any symptoms from which they may be suffering are dangerous or not and to go forthwith to their doctor for confirmation; and to convince them to consult a person thoroughly qualified to give them an honest and experienced opinion." The aim is worthy, but perhaps more difficult of achievement than the author has realized. His presentation is, no doubt designedly, dogmatic and his wording brief. This easily leads to occasional statements which to the doctor are not strictly accurate, and to the layman may be misleading; and it does not lend itself to a clear distinction between symptoms and signs which suggest quite rare conditions, or serious conditions, and those which indicate disorders of less moment. If the book proves to supply a real want of the public a little expansion might remedy these defects, and at the same time more emphasis might be placed on preventive measures of personal hygiene, such as those briefly mentioned in the last chapter on baths and cleanliness, on ventilation, on clothing, and on exercise.



The ninth volume of the *Guide to Current Official Statistics of the United Kingdom* contains a list of the statistical publications issued during 1930 by Government departments in Great Britain and Northern Ireland, together with an index of their contents arranged alphabetically according to subject, with information of the time and place to which the statistics relate. It is therefore possible to discover without delay the official statistics available for any particular purpose, and the names and prices of the publications in which they are to be found. The volume is obtainable at H.M. Stationery Office, price 1s. net.

PREPARATIONS AND APPLIANCES

A SIMPLE FASCIA CUTTER FOR LIVING SUTURES

Mr. A. WILFRID ADAMS, M.S., F.R.C.S. (Clifton), writes:

The instrument shown in the accompanying figure was designed to obviate the long incision down the thigh necessary for procuring strips of fascia for hernioplasty, etc. It works subcutaneously, does not get out of order, and is cheap. At the outset I experimented with Mayo's vein enucleator, and on that idea the fascia cutter is modelled.

Cutting is effected by tiny knives, which form the sides of the fenestrated end of the long steel shaft, which is 16 inches long. The handle is at an angle of 15 degrees with the shaft.

A 2-inch vertical incision is made over the fascia lata at the knee. After exposing it an end of fascia is raised of the required width, 1/4 to 1/2 inch, and is then pulled through the opening in the cutter by a pair of artery forceps. While the forceps hold it taut, the cutter is driven subcutaneously upwards and towards the great trochanter. The progress is automatically arrested by the bulky flesh of the tensor fasciae femoris blending with the origin of the fascia. At this stage the upper end of the cutter is made prominent by pressing the handle against the patient's knee. A transverse incision, 1 inch long, through the skin at the prominence reveals the cutter carrying the upper end of the fascial strip. It is easy to divide and then withdraw the latter ready for use as a suture; adherent fat, if any, is cleaned off it.

Many such sutures may be prepared by an operation which takes five minutes and has been free from complications.

Messrs. Allen and Hanburys have manufactured the instrument for me.

A TWO-PIECE GLASS SYRINGE

We have received from Messrs. Burroughs Wellcome and Co. a two-piece "Agla" syringe, graduated in minims and tenths of 1 c.cm. It is made of glass, and the blue tip of the piston enables one to tell at a glance the quantity of fluid in the syringe. Fitted with a rustless steel needle (protected by a metal guard) the assembled syringe fits closely into a glass container filled with spirit, the piston acting as a stopper. The whole is enclosed in a cylindrical metal case which can be clipped on to the pocket. The spirit and containing tube can be replaced in the metal case without risk of spilling while the syringe is in use. This type of syringe is supplied in 1 c.cm., 5 c.cm., and 10 c.cm. sizes, with a model graduated in twentieths of 1 c.cm. for insulin administration. It is very convenient for hypodermic emergencies

SATURDAY, AUGUST 1st, 1931

THE EASTBOURNE MEETING

One more Annual Meeting of the British Medical Association has come and gone, and the members who attended it have nothing but happy memories of their week of work and play in the tonic sea-coast air of Sussex. As there is thought to be some peculiar diagnostic significance in the number "99" we have put the ninety-ninth meeting to the test of auscultation, and are able to report that the voice of the medical visitors to Eastbourne was clear and resonant and unanimous in praise of all the arrangements; and we may add that no other method of examination could detect a trace of dullness anywhere among the social proceedings. If the amount of sunshine earlier in the week fell short of Eastbourne's proverbial record, this was more than made up for by the warmth of the welcome which the local profession and the municipality offered to their guests. Not the least agreeable feature of an enjoyable meeting was the obvious pride and pleasure felt by his colleagues and fellow townspeople in the circumstance that their honoured friend and leader Dr. W. G. Willoughby should be the first full-time medical officer of health to hold office as President of the British Medical Association.

The attractions of Eastbourne as a well-ordered health resort, and the fact that many members had been unable to travel to Winnipeg last year, assured a good and very appreciative attendance, including delegates from Branches and Divisions in distant parts of the Empire. It was a matter for real regret by everyone that Professor Harvey Smith could not undertake the long journey from Canada and install his successor in the presidential chair. We have already begun publication of detailed reports of the medico-political and other professional work of the Annual Meeting; here it will suffice to say that many valuable communications were made, and that, through the accounts printed widely in the newspapers, much public attention was focused on the debates in the Representative Body and afterwards on the less technical papers discussed in the fourteen Sections. Taken as a whole, the clinical and scientific topics chosen for discussion this year were of more than usual interest from the point of view of general therapy and diagnosis. Several of the introductory papers are published in full to-day in our opening pages; the others will follow week by week until the end of the year. It was a great convenience to those wishing to make the best use of their time that all but a few of the largest Sections held their meetings under one roof in the class-rooms of Eastbourne College, near the reception room and the exhibition of drugs and appliances at Devonshire Park; and that the Pathological Museum, with its instructive collection of specimens bearing on the work of the Sections, was housed little more than a quarter of a mile away at the Technical Institute.

No previous Annual Meeting has been better served in the matter of street signs and other aids to locomotion, and for its effective help in this and other ways a word of thanks is due to the Automobile Association. But the organization throughout was admirable. All contingencies had been foreseen and provided for by the local Executive; the quiet, unhurried efficiency of the staff work must have been plain to everyone except perhaps to the sort of person (rare, we hope, among doctors and their families) who takes such things for granted. Where, as at Eastbourne, a considerable number of men and women worked together as a team, it seems invidious to pick out two or three for mention, but the Honorary Local General Secretary, Dr. P. W. Mathew, bore so large a part of the burden before and during the event that his name must be printed here in grateful recognition, and with it that of his deputy, Dr. H. G. Estcourt. Special acknowledgement should be made also to the Mayor, Lieut.-Colonel R. V. Gwynne, both for what he did in his official capacity on many occasions, and for his personal share in entertaining visitors. The Annual Meeting of 1931 will long be remembered for its entertainments (in particular for the delightful functions at Devonshire Park and at Folkington Manor, where the Mayor and Corporation acted as hosts), and for the number and variety of well-planned excursions to places of interest in the county of Sussex. It is right that this side of the proceedings should be brought out in a brief general review, because while the political and scientific business is fully reported, the social activities, which mean so much to the success of a large conference of this nature, cannot claim record in the same detail.

It was evident to all who took part in the Annual Meeting of 1931 that Eastbourne welcomed with both hands the opportunity to act as host to the British Medical Association. The Association had never met there before, and in the nature of things it must be many years before it pays a second visit. The guests of Eastbourne are grateful for the material good things offered them in abundance last week by Dr. Willoughby and his colleagues, and they appreciate even more that intangible grace which is the soul of true hospitality.

THE OUTLOOK OF INDUSTRIAL MEDICINE

The thoughtful and suggestive paper with which Dr. L. P. Lockhart opened the discussion in the Section of Public Health at Eastbourne, and which we print this week, cannot fail to have impressed all who heard it, and is so important that the attention of our readers may well be specially directed to it. The title, "Industrial problems from the standpoint of general practice," scarcely does justice to the fullness of its content, the freshness of its outlook, and the far-reaching effects of its conclusions. It should be of special interest to general practitioners. In his Presidential address to the Association Dr. Willoughby

pointed out that the very office of public health medical officer was one of the developments rendered possible only by the general advance in the science and art of medicine, and that the work of the general practitioner in the sphere of preventive medicine was ever becoming more important and extensive. So Dr. Lockhart, regarding industrial medicine as something much wider than the mere problem of occupational disease, declares that " the day of the general practitioner is not waning but only dawning. In his hands lies the ultimate responsibility for co-operating with the public health services in extending the boundaries of their mutual spheres in order to produce the harmonious integration of those mental, physical, and spiritual factors whose combination forms the only possible basis for intellectual growth and adaptive development. This constitutes a field of study of supreme importance to the general practitioner."

Dr. Lockhart's main thesis, cursorily summarized, is that the industrialization of Western civilization is so recent and has been so rapid that man is very imperfectly adjusted to his new environment, that " racial memory dies hard, and in our modern world there are countless relics of primitive magic—charms and taboos—which have no claim in reason, but which exert their influence through the operation of inherited feeling states. The fear of Nature as an instrument of divine wrath has been replaced by a new fear—that of the complex mechanism of modern life which crushes remorselessly those who fail to pay it homage." This leads to " neurosis, warped judgement, loss of individuality, and to a tendency to clutch fearfully at the *status quo* as it slips inevitably from our grasp." We have survived the first effects of industrialism on the physical environment—congestion, slums, and all that follows in their train—and the explanation of the present unsatisfactory state of the public health and of the increased sickness of recent years is largely psychogenic, revealing a state of mind which is widespread and productive of a great amount of incapacity. " The vast machine of modern life is at times a terrifying thing. In the face of such forces as unemployment, mechanical displacement of labour, the competition of girls with men and their success in handling machines and executing small repetitive processes at lower cost, the economic difficulties of the home and resulting problems of sexual adjustment, there is a tendency for many to develop a feeling of inadequacy to life which is liable to be rationalized in consciousness as illness rather than to be acknowledged frankly for what it is—namely, a fear of the unknown and the intangible. . . . In industry compensation for accident and disease is being sought as an end in itself rather than as a means towards restored function." Seen thus against the background of modern industrial civilization, with the vast uncertainties and seemingly inexorable power of its daily movements, there seem to be two outstanding reactions of the mind—fear, and a sense of inferiority. With the appearance of a wholly novel set of anxiety problems, certain props have been removed. Ignorance has been exposed and theological dogma is collapsing. The education of the young is as yet often misdirected, and " that natural intimate and personal religious experience which is a supreme and vital human necessity " is in large numbers of men and women not realized or developed.

Few will dissent from Dr. Lockhart's conclusion that at least a prima facie case has been made out for reviewing the whole situation afresh from a psychological standpoint, and that " if we wish to hold our own in the modern industrial world we must do something about it, not only effectively, but at once." It cannot be denied that full health is at least as much a mental as a physical matter, and that incapacity or otherwise may depend very largely upon the spiritual outlook. It has been emphasized in our columns that health and education are but different aspects of one subject, and that medical practice is not a thing by itself, apart, but may be regarded as one social service among many others with which it is increasingly bound up. Dr. Lockhart reinforces this point. Believing that " the burden of sickness, which is not only causing vast loss of time and money by actual absence, but which is sapping the general vitality of a far greater number than those who actually go sick, is in the main a psychological problem," he maintains that " it is necessary for us all, whether we consciously practise psychotherapy or not, to grasp the essential workings of the mind which modern research has unfolded." He points out how much can be done by a progressive Church and an enlightened scheme of education, and presses for the co-operation of the general practitioner. The industrial clinic, he says, either in a large factory or in a group of smaller ones, can be a very important link in the chain of public health work, but it can only serve its true purpose by collaboration with general practitioners and educationists. He believes that the future of public health lies as much in the hands of general practitioners as in those of medical officers. " For this purpose both must study industrialism and human psychology—not so much to practise psychotherapy, but to understand why men act and react as they do." It is probable that in ordinary medical practice, perhaps especially in hospital practice, too little regard is paid to the psychological aspect of illness. This aspect may explain much that seems mysterious in the recent increase in sickness claims, and it is well that Dr. Lockhart should so emphatically have insisted on its importance.

CANCER DIAGNOSIS BY SPECTRO-PHOTOMETRY

Dr. S. G. T. Bendien of Zeist, Holland, claims to have elaborated a laboratory method for the diagnosis of carcinoma, and a representative of the British Empire Cancer Campaign (Dr. Alfred Piney, secretary of its Investigation Committee) has personally begun an investigation of this matter. Dr. Piney travelled to Holland with thirty-eight tubes of blood serum which had been collected by an independent physician from patients suffering from certain diseases such as cancer, diabetes, and rheumatism ; with them were some specimens of serum from normal persons to serve as controls.

This physician had prepared a list of the diagnoses, which was placed in a sealed envelope Dr Bendien was able to examine only twenty-one of the specimens, five of which he diagnosed as being the serums of patients suffering from carcinoma When his diagnoses were compared with those in the sealed envelope they were found to correspond In one instance he made a tentative diagnosis of carcinoma , this patient was a man on whom prostatectomy had been performed, but unfortunately no histological report was available It appears that Bendien's technique consists of two parts The first is a flocculation method in which the serum is precipitated with various mixtures of acetic acid and sodium vanadate , the precipitate is dissolved in 2 per cent sodium bicarbonate solution, which is submitted to spectro photometric examination From a series of spectrograms the extinction coefficients are obtained, and it is on the basis of the curve so plotted that the diagnosis is made [1] Dr Bendien's view is that cancer is a local disease which can develop only if a specific abnormality of the serum is present He has expressed the hope that it may be possible to elaborate a therapeutic method capable of causing such abnormal serums to become normal, and thus unsuitable for the growth of carcinoma He is not satisfied yet that he can obtain an accurate diagnosis in every case of carcinoma, but he claims that a positive reaction is never seen in cases of any other disease A matter of very considerable interest is the fact that Dr Bendien has been unable to discover any specific characters in the serum of cases of sarcoma The British Empire Cancer Campaign, while agreeing that a definite advance in the diagnosis of cancer appears to have been made, issues the very necessary warning that some time must elapse before the full value of the method can be ascertained A careful investigation is being started immediately at the Cancer Hospital, London

JUVENILE CRIME

The Home Office Report on criminal statistics for England and Wales in 1929[2] embodies an interesting introduction in which, among other things, an attempt has been made to determine the factors underlying the increase in certain crimes In 1929 the number of indictable offences known to the police was 134,581 or 4 112 more than in 1928, the incidence per million population having risen from 3,305 to 3,398 This rise is continuous with similar rises that have occurred since the war There was a marked decrease in the number of persons over 16 charged with indictable offences during the years 1914–18 , after the armistice the figures went up again, but have now fallen to the pre war level The number of juveniles charged, however, was doubled during the war, fell directly after its close, and has recently tended to rise The introduction of the Probation of Offenders Act has swelled the numbers of those juveniles, dealt with in the juvenile courts whom magistrates in 1907 were reluctant to convict But even allowing for this, the figures are startling In 1907 the number of boys under 16 convicted was 6 956 , in 1929, with a male population in this age group 12 per cent less, the number was 10,382—an increase of 49 per cent A comparison of other age groups with the above is interesting In 1907, for example, 7,728 males between the ages of 16 and 21 were convicted, and in 1929 the number was 9,209 The total and relative numbers for the age groups 30–40, 40–50, and over 60 were actually smaller in 1929 than in 1907 In the juvenile class the crime which attracted most offenders was shop-breaking, and in the same class of boys under 16 there were two and a half times as many sexual offences in 1929 as in 1907 What has been the cause of this increase in juvenile crime? According to the statistics, which show an exemplary decrease in crime in men over the age of 30, it would not appear to be due to boys imitating their fathers, or, for that matter, their mothers, as there has been an unequivocal decrease in crime among mature adult women in the twenty-two years from 1907 to 1929 "This fall," the present report states, " confirms the view that in spite of woman's increased activities the total volume of crime among women has not increased " Would not the substitution of *because* for *in spite of* represent the true state of affairs? The great rise in the number of juvenile offenders during the years 1914–18 is reasonably attributed to the intermittence of parental control under war conditions " It does, however, appear," the report continues, " that during the last few years there has been an increase in juvenile crime, and it remains to see whether some factor, operating decisively since the war, has gone to increase the juvenile crime rate " This factor Mr Arthur Locke, who prepared the introduction to the report, considers to be industrial depression There are a few points, however, which appear to us to indicate that this is by no means the whole truth During the general strike in 1926, for example, the greatest rise in the crime rate was in persons over the age of 16 Of these, the greatest percentage rise (75 per cent) was in the age group 16–21, a group which, as the report points out, constituted the juvenile group of the war years So that during one of the greatest industrial crises of the post-war period the main increase in crime was in the age groups over 16 The children aged 15 in 1929, the year under consideration, were born in 1913–14, and so passed the most impressionable years of their lives during the war In the early part of 1918 the first epidemic of encephalitis lethargica made its appearance in Great Britain, and between 1919 and 1925 there were 12,054 notifications of this disease Cases wrongly diagnosed as influenza, etc , especially at the beginning, constitute an undetermined number It is well known to what extent behaviour disorders occur in children as a sequel of encephalitis lethargica and this is now recognized by magistrates , but how many juvenile criminals are examined by doctors specially qualified in neurology or psychology or in both? We suggest, then, that the inclusion of the four war years in those first most impressionable seven years of childhood, and the after effects of encephalitis lethargica, are two factors which must be taken into consideration in any study of juvenile criminality An interesting comparison between the crime incidence in the North and South of England shows a definite increase in the North where the industrial depression is most severe. On the other hand, in the South there has been a

[1] Bendien S G T *Specifische Veränderungen des Blutserums Carcinom Fischer* 1931
[2] Criminal Statistics England and Wales 1929 London H M Stationery Office 1931 (3s 6d net)

growing tendency among men of the age group 21–30 "to commit crimes of adventurous lawlessness and violence." More people attempt to commit suicide. In 1921 the number was 1,380; in 1929 it had risen to 3,094. Taking all things into consideration Mr. Locke concludes that "the general outlook appears to be not unfavourable."

INTERNATIONAL UNION AGAINST TUBERCULOSIS

The annual meeting of the council of the International Union against Tuberculosis, whose chairman is Professor Frölich (Norway), was held in Paris on July 9th, when delegates from seventeen countries attended. It was decided that the next conference of the Union would be held at The Hague from September 6th to 9th, 1932, and that the three following subjects, selected from a list of questions submitted by the various countries belonging to the Union, would be inscribed on the agenda. Biological subject: "The relationship between allergy and immunity"; the opening report will be read by a person to be designated later. Clinical subject: "Gold therapy," opening report by Professor Sayé (Barcelona). Social subject: "After-care schemes for the tuberculous," opening report by Dr. B. H. Vos (Hellendoorn). According to the method adopted at the Oslo conference, ten speakers, chosen from different countries, will be designated to open the discussion on each of the three main subjects. The scientific session was held at the Pasteur Institute, in the new tuberculosis laboratories, which the members of the council visited under the guidance of Professor Calmette. The meeting was devoted to the report of Dr. Soper (United States) on "A standard anti-tuberculosis plan," read in his absence by Professor Opie. Professor Valtis (Greece) then explained the steps taken in regard to the anti-tuberculosis campaign in his country. These reports were followed by a discussion in which Professor Léon Bernard, secretary general of the Union, Professor Knud Faber (Denmark), Colonel Rudzki (Poland), and others took part. On the same evening the members of the council dined at the Indo-Chinese pavilion in the Colonial Exhibition, where they were the guests of the French National Committee for the Campaign against Tuberculosis. M. Blaisot, Minister of Public Health, attended, and in the name of the French Government gave an address of welcome to the members of the council.

EDWARD JENNER AND OTHER NATURALIST-PHYSICIANS

At the Cambridge meeting of the British Medical Association in 1880 Sir Michael Foster, in his address on physiology, showed that all distinctions between it and pathology were fictitious, and illustrated this thesis by inquiring what would be said of the kindred science of meteorology if it were divided into separate sciences of fine and foul weather! Sir William Gairdner took "The physician as naturalist" as the title for his introductory address to the medical students of Glasgow in 1882, and quite recently Dr. J. A. Ryle spoke to the Cambridge University Medical Society on the same attractive subject. Of the broad-minded attitude which regards medicine as human biology and encourages medical men to be students of nature there have been many exponents in the past, and of these Edward Jenner, whose *Note-Book*,[1] now in the possession of the Royal College of Physicians of London, and published with an introduction by Dr. F. Dawtrey Drewitt, is an outstanding example. It is doubtful if Jenner could have a more sympathetic and suitable interpreter than the author of the charmingly written *Romance of the Apothecaries Garden in Chelsea*, now deservedly in a third edition, who has undertaken this labour of love at the request of Sir John Rose Bradford when President of the Royal College of Physicians of London. As an ornithologist-physician Dr. Dawtrey Drewitt has given an account, at once authoritative and intriguing, of the immoral habits of the mother cuckoo and her offspring, and it does not demand much stretch of imagination to recognize the personal touch in the following paragraph:

> "Very many years ago—probably it is so now—if a boy at Winchester, during the months of May and June, put on his football dress, and waded up to his waist among the reed-beds in the River Itchen, he could always find reed-warblers' nests suspended in the reeds, and containing cuckoo's eggs. In colour and markings their resemblance to the other eggs in the nest was striking."

In the reference to Jenner's observations on the order in which birds begin their morning songs the commentator cheers the reader by the kindly message that "the early-morning-wakefulness of advanced age does not trouble the old naturalist." Jenner's *Note-Book* from 1787 to 1806 records a number of experiments on exchanging eggs in the nests of different birds, describes necropsies on birds, including the cuckoo, and observations on the incidence of hydatids. The history and description of this manuscript note-book, now printed for the first time, are provided by A. C., initials which happen to be the same as those of the Harveian Librarian of the Royal College of Physicians of London.

THE PROPHYLAXIS OF LEPROSY

In the first general report of the Leprosy Commission of the League of Nations Health Organization Dr. Burnet, the secretary, summarizes the conclusions reached after several years' investigation of this problem in both the Eastern and Western Hemispheres. In the light of recent advances made as the result of the improved treatment of leprosy, it is now possible to lay down general lines of prophylaxis, subject to modifications according to local conditions in different countries. The new outlook on this ancient problem is emphasized by the subject of "treatment" being first dealt with as "the most important line of attack, in addition to that by isolation," which was for many centuries the only prophylactic measure, but one which may now be gradually made less rigorous. The removal of debilitating diseases, a diet rich in vitamins, and exercise, are also necessary. The use of ethyl esters and soaps of chaulmoogra oils is declared to be the chief method of special treatment, although further technical studies in this matter are required. The serious drawback of isolation is that it promotes con-

[1] *The Note-Book of Edward Jenner*, in the Possession of the Royal College of Physicians of London. With an introduction on Jenner's Work as a Naturalist by F. Dawtrey Drewitt, M.D., F.R.C.P. London: Milford, Oxford University Press. 1931. (3s. 6d. net.)

[2] League of Nations Health Organization. The Principles of the Prophylaxis of Leprosy. First General Report of the Leprosy Commission. Geneva, April, 1931. London: G. Allen and Unwin. 6d.

cealment of cases, with delay in the all important early treatment, this should be overcome by applying it only to those which are infectious, and by permitting early uninfective cases to be treated as out patients at dermatological clinics when numbers are small, or, when great, at special leprosy clinics To ensure this, all medical students, medical practitioners, and health officers in leprous countries should have special courses of instruction in the modern treatment of leprosy, and every such country should have at least one centre for the clinical and scientific study and teaching of leprosy, and for the organization of propaganda to combat "indifference" to the disease on the one hand, and "blind panic" on the other, and "to bring home to the people that leprosy, though contagious, is a remediable disease, resembling tuberculosis in this respect" Uninfective patients may require to be provided for in special colonies, and all discharged and apparently recovered patients should be kept under surveillance and periodically re examined The children of lepers should be removed from their parents as soon as possible after birth, especially when born in leper institutions, where marriages and the propagation of children should be discouraged in every way possible School children in leprous countries should be examined for symptoms and removed for treatment in the earliest stage of the disease These propositions will receive general endorsement by modern leprologists, as will the conclusion that "there is no reliable system of prophylaxis without treatment, and it is generally accepted that the earlier the treatment is instituted the better will be the results"

MEDICAL RESEARCH COUNCIL

By an Order of the Committee of Privy Council, made after consultation with the Medical Research Council and with the President of the Royal Society, the Right Hon Lord Dawson of Penn, G C V O, President of the Royal College of Physicians, and Extra-Physician to the London Hospital, and Dr Edward Mellanby, F R S, Professor of Pharmacology in the University of Sheffield, are appointed members of the Medical Research Council in succession to Professor T R Elliott, F R S, and Professor J B Leathes, F R S, who retire in rotation on September 30th

DEATH OF LORD KNUTSFORD

We have to announce with deep regret that Viscount Knutsford, chairman of the London Hospital and of the Research Defence Society, died suddenly on the evening of Monday, July 27th, within the walls of the great hospital which he served for many years with such conspicuous ability and devotion He had been ill for several weeks, and lately underwent a severe operation We hope to publish a memoir next week.

ANNUAL MEETING NOTES

RECOGNITION OF DR. COX'S SERVICES

The first meeting of the general committee, called together on the initiative of Dr E R Fothergill of Hove to conduct the project for recognition of the services of the retiring Medical Secretary (Dr Alfred Cox), was held at Eastbourne after the close of the session of the Annual Representative Meeting on Saturday, July 18th The members of the general committee already number over 140, and the oversea members' list is incomplete There was a very large attendance at the meeting Dr H G Dain (Birmingham) was elected temporary chairman

Dr Fothergill said that he had received a large number of letters, all of them approving the proposal, and some containing practical suggestions Discussion first took place on the election of chairman of the general committee The first name proposed was Sir Robert Bolam, who said however, that while nothing would give him greater pleasure than to support the movement in every way possible, he felt there was a distinct advantage in appointing as chairman someone outside the official circle of the Association, and who could be said to represent the profession at large Dr Brackenbury and Dr Hawthorne spoke to the same effect Eventually it was proposed and unanimously agreed to that Sir Humphry Rolleston be approached with a view to taking the position of chairman of the general committee, which would carry with it membership *ex officio* of the executive presently to be appointed Certain proposals as to the form of recognition were then brought forward by Dr Fothergill on the basis of opinions which he had collected in correspondence

It was agreed after a brief discussion, that a fund be formed to provide the British Medical Association with a painting in oils of Dr Alfred Cox to provide Dr Cox himself with a cheque, and, if he desired it, with a copy of the painting, that steps be taken to engage an artist of the first rank, and that arrangements be made whereby medical bodies and members of the medical profession would be enabled to purchase, if so desired, an engraved copy or photogravure of the painting, which should be autographed by the sitter The amount of the subscriptions to be expected from each member was then discussed After Dr Brackenbury and others had stated that the recipient would almost certainly appreciate a large number of small personal subscriptions, rather than large amounts of a less personal character, it was agreed that directly and through the medical press an appeal should be made to members of the British Medical Association for subscriptions not exceeding ten shillings per member, and that while accepting subscriptions from medical societies, local medical and panel committees, and non members of the Association, no direct appeal be made to such It was also agreed that the names and addresses of subscribers to the fund should be entered in a book for presentation to Dr Cox The meeting then proceeded to the appointment of the nucleus of an executive committee, and the following names were agreed to

Chairman Sir Ewen Maclean
Treasurer, Mr Bishop Harman
Honorary Secretary, Dr E R Fothergill
Members Dr Brackenbury Dr Dain Dr C O Hawthorne, Dr Arnold Lyndon Dr Christine Murrell Sir StClair Thomson and Dr W G Willoughby

It was agreed that these should have power to co opt others, and it was announced that the first meeting of the executive would be held the following evening to begin to take steps to carry into effect the above recommendations, and to take such action as might be necessary to complete the proposal at the time of the Centenary Meeting The meeting accorded a hearty vote of thanks to Dr Fothergill for his action in the matter For Sir Ewen Maclean's statement on this subject at the close of the Annual Representative Meeting, and the discussion thereon, see the *Supplement* this week (p 116).

POPULAR LECTURE: DISEASES OF ANIMALS TRANSMISSIBLE TO MAN

The final event of the Annual Meeting week was the Popular Lecture, which was delivered in the Town Hall, Eastbourne, on the evening of July 24th, by Professor F. T. G. Hobday, Principal and Dean of the Royal Veterinary College. The chair was taken by Dr. W. G. Willoughby, President of the Association, and there was a large audience, which almost filled the assembly room.

Professor Hobday said that there were at least two very obvious reasons why those who owned, or associated with, animals should keep them as far as possible in good health. The first was for the sake of the animal itself, on both sentimental and economic grounds, and the second was on the ground of public health, in view of the transmissibility of certain animal diseases to man. Prevention was always better than cure, and as many of these diseases could be prevented, to be forewarned was to be forearmed. This subject was of importance not only to the agriculturist who dealt in live-stock, but also to the townsman who kept domestic animals as pets. One recent illustration was afforded by the outbreak of psittacosis, a disease derived from parrots, from which a number of human beings had died, with the result that not only had a large number of parrots in England been destroyed, but cargoes of the birds from South America were still forbidden to enter the country. That was only one example of the necessity for interchange of experience between practitioners of human and veterinary medicine. It often happened that the veterinary practitioner was asked to state the extent of the risk run by children when the domestic dog or cat became ill, or when there was some contagion which made it advisable to isolate the animal.

The lecturer, whose remarks were illustrated by lantern slides and by a cinematograph film, put aside the large field concerned with tropical disease, and concentrated on diseases of the horse, cow, dog, and cat. From the horse, he said, sundry diseases might be contracted, the chief of which were glanders, mange, and ringworm. Glanders had now disappeared from Great Britain, having been stamped out entirely by the measures taken under the Contagious Diseases of Animals Act, administered by the Veterinary Department of the Ministry of Agriculture. Only twenty years ago some 1,800 horses in London alone were slaughtered on account of this disease, and eight or nine persons died annually from glanders contracted from the animal. In the South African war many thousands of animals had to be destroyed on account of glanders, but in the European war, notwithstanding the great numbers of horses employed, glanders was completely eradicated. This was due to the rigorous application of what was known as the mallein test for glandered horses, whereby it was possible to tell whether a horse had even a single nodule of the size of a pin-point. So effective was this test that when the war was over more than 70,000 Army horses were sold to the British public, and yet no case of glanders was reported. Glanders, when it reached the human subject, was one of the most fatal of illnesses. Formerly it was specially dreaded in cab and omnibus stables, but now, owing to the effective supervision, it had disappeared from horses, and consequently from human beings also. Mange and ringworm in horses were also transmissible to man, and other animals which could pass ringworm on to the human subject were the cat, the rabbit, and the hedgehog.

The next great problem of veterinary science was the presence of tuberculosis in the cow. That cattle suffered from tuberculosis was well known to all who had to do with animals on a farm. At the present moment there were about one million tuberculous cattle in England; it must not be taken, of course, that these were all dairy cows, with regard to which supervision was very strict. New regulations compelled the owner of a dairy cow having anything wrong with the udder to call in a veterinary surgeon. Here, again, in bovine tuberculosis, a most insidious condition, the necessity was illustrated for close co-operation between human and veterinary medicine. America was far ahead of us in measures for dealing with bovine tuberculosis, and in very many districts of the United States there were herds guaranteed free from the condition. It might be asked why tuberculosis was not eradicated here by destroying all cattle suffering from the disease, but to destroy a million tuberculous beasts would mean an immediate shortage of beef and milk, and the problem was not quite as simple as it might at first appear. There were, however, numerous herds in this country which were free from the disease. If hospitals, general practitioners, and housewives would unite in demanding that milk must be guaranteed tubercle-free, it would greatly accelerate matters. The milk supplied to households should be of Grade A (T.-T.) quality —that is to say, free from tuberculosis. The mere fact that it was Grade A was not a sufficient guarantee. In other countries, notably Germany and Russia, all meat went to the public abattoirs, but in England there remained a certain number of private slaughterhouses, and some of these were not as strictly supervised as they ought to be. If we were not a people who cooked our meat to the extent we did, tuberculosis would be much more widely contracted from eating tuberculous meat.

Anthrax, foot-and-mouth disease, and cow-pox also could be transmitted from cattle to man. Anthrax was a very serious condition. In Bradford and other centres where wool from other countries was handled, disinfection was insisted upon. If once anthrax were eradicated from the animal, its eradication from man would follow, for it always originated from an animal or an animal product. The prevalence of foot-and-mouth disease had led to a good deal of misleading and unjust criticism in the public press of the veterinary advisers to the Ministry. Although the cost of dealing with outbreaks of foot-and-mouth disease amounted to a very considerable sum, it was a mere flea-bite compared with what might have been, and with what in fact was, the cost in other countries, notably Holland, Germany, Belgium, and Denmark. There not only was the cost very much greater than here, but they never seemed to get any nearer to exemption. Professor Hobday produced a table showing that in England last year there were only eight outbreaks of foot-and-mouth disease (seven in September and one in November), whereas in Germany and Holland as many as 5,000 outbreaks were recorded in a single month.

Turning to the dog and cat, he said that rabies was by far the most dreaded of all the diseases to which the dog was subject, and both the medical profession and the general public had reason to be grateful to the veterinary surgeon because this disease had been eradicated and prevented from readmission into this country. The measures taken involved some days in quarantine for the animal, but that was surely better than to allow the possibility of the importation of animals which would spread the disease. Like glanders in the horse and rinderpest in cattle, which formerly cost this country great sums, rabies in the dog and cat had disappeared, and as long as the veterinary experts of the Ministry were allowed to carry out their duty in this regard, so long would the practitioner be able to tell a patient who had been bitten by a dog or cat that he need have no fear of this terrible consequence. A disease which was transmissible from the dog or cat to man was follicular mange. If one fondled a dog or cat suffering from this "itchy" condition, the parasite of mange might transfer itself, and although something prevented it from breeding in the human host, it would live out its life-cycle under the skin, perhaps for

about forty days, so that discomfort would persist for that time, apart from the possibility of fresh infection from the same source In Egypt mange was frequently caught by attendants on camels He mentioned one case in which the attendants, the night being cold, covered themselves with the camel cloths, and suffered a severe infection with follicular mange In conclusion, the lecturer said that there were a number of other diseases in animals which, although not recognized as definitely contagious, had their interest from the point of view of the public health service Cancer, for example, was recognizable in horses, dogs, cats, birds, and even in fish, and it had often happened that theories on which research workers had proceeded on the basis of observation upon human beings alone had been proved to be erroneous when comparative medicine was studied

THE OFFICIAL RELIGIOUS SERVICE

The religious service at St Saviour's Church, Eastbourne on the afternoon of Tuesday, July 21st, was preceded by a brief ceremony at the war memorial, whither the members went in procession, wearing their academic gowns, and preceded by the symbolic staff The Mayor and Town Council headed the procession, which included also the Bishop of Chichester and clergy A wreath was deposited at the foot of the memorial by Dr Willoughby, the President, and after prayer the "Last Post" and "Reveille" were sounded, and the procession returned to the church, where a brief but impressive service was held The Lesson, from the Wisdom of Solomon, was read by the President, Dr Willoughby It was followed by Charles Kingsley's hymn, "From Thee all skill and science flow," after which the sermon was preached by the Bishop of Chichester Dr Bell based his sermon on a passage taken from the Lesson "All things that are either secret or manifest I learned, for she (Wisdom) that is the artificer of all things taught me" Wisdom, he said, was, to begin with, learning, for it could hardly be said to exist without a knowledge of the facts The knowledge of the physician was certainly intended in the catalogue of that which the wise man knows, for the wise man, in this old Wisdom of Solomon, had "an unerring knowledge of the things that are the natures of living creatures and the ragings of wild beasts the violences of winds and the thoughts of men, the diversities of plants and the virtues of roots But wisdom for the physician, the Bishop continued, was not only the learning of facts, which might by themselves be of little use, wisdom was the possession of the principles behind the facts and governing the facts, and an insight into the constitution of man's body The good physician in all his work was governed by law He proceeded according to the laws of science—and wisdom was science "Physicians are like kings, said Duke Ferdinand in Webster's play, "they brook no contradiction" Those of them who were patients appreciated the truth of that remark, but the patient assented to the doctor's direction because he knew that the doctor himself was under authority—the authority of the laws of science and the laws of nature which, like kings, brooked no contradiction To obey these laws, whether in general practice, in the consulting room, in the hospital as medical officer of health, or as a research worker, was to be the servant of wisdom, to disobey them, or to forget their application to a particular condition, was not only to do injury to the patient's life, but to sin against wisdom There was, however, a further aspect of this service of wisdom which the ancient writer held to be the deepest of all Wisdom, he said, was 'the breath of the power of God, the unspotted mirror of the work of God, and the image of His goodness" To be a servant of wisdom, therefore, from this deepest point of view, was to be a worshipper of God, even as it were a living being through which the breath of the power of God was breathed Wisdom was thus to be linked up with the source of life itself It was dangerous for a layman, continued the Bishop, to attempt even a humble excursion into scientific fields, but he hoped that without undue rashness he might suggest that some little light was thrown on what he was trying to set forth by the words of William Harvey, in his treatise on the motion of the heart, in which he compared the heart to the sun, which might be designated the heart of the world, "the household divinity which discharges its functions, nourishes, cherishes, quickens the whole body, and is indeed the foundation of life, the source of all action" Substitute 'wisdom" for 'the heart,' and apply it to the whole scheme of things, and his congregation would see the situation which he was trying to reveal Men of science like those he was addressing, just because of their acquaintance with the facts and their knowledge of the laws which governed the natural world, should find it far less difficult than ordinary folk to perceive wisdom to be the 'household divinity' in the constitution of the universe, discharging those functions of which Harvey spoke "I am moved to offer these reflections, concluded the preacher, "because it is surely well, in the midst of the Annual Meeting, necessarily taken up with questions of business and administration, including issues of a more controversial character, to let the mind rest for an hour on those deep truths on which all faithful practice is founded You hold this service year by year, wherever you assemble, as an acknowledgement that in following your vocation you are servants and worshippers of the Almighty" The service concluded with a collection taken for Association charities

THE LAPARO-TRACHELOTOMY FILM

On the afternoon of Wednesday, July 22nd a large gathering assembled at the Town Hall Eastbourne to witness a "sound film illustrating the technique of the lower uterine segment Caesarean section The operation was performed and the explanatory talk in connexion with it was given by Dr Joseph B De Lee of the Chicago Lying in Hospital The film began with a description by Dr De Lee of the indications for the operation, and the surgical anatomy of the parts involved He strongly recommended the employment of local infiltration anaesthesia, adding that he never used any other himself the sites for injecting and the method of making the injections were very clearly shown A close up view of the procedure in all its stages followed films of operations on several different patients demonstrated particular forms of difficulty—for example, the technique required when the vertex or breech presented or the presenting part had sunk well down into the pelvis The film provided a remarkably vivid illustration of the various stages of the operation, its exhibition was due to the courtesy and enterprise of the Western Electric Company After it had been shown there was an informal discussion, during which it was mentioned that there was in Chicago, in course of erection, a medical institute in which all the operating theatres and clinics would be equipped for the preparation of sound films with the special purpose of aiding post graduate instruction It was generally agreed that this kind of film offered extraordinary facilities for supplying to medical practitioners widespread instruction in medicine and surgery even if they could not spare time to attend regular post graduate courses at recognized training centres

The number of members who registered their attendance at the Annual Meeting this year was 1,163 This total does not include ladies accompanying members

NINETY-NINTH ANNUAL MEETING

OF THE

British Medical Association

Held at Eastbourne, July, 1931

THE SECTIONS

SUMMARY OF PROCEEDINGS

During the next few months there will be published in the *British Medical Journal* the opening papers communicated to the Scientific Sections of the Annual Meeting at Eastbourne. The summaries of discussions in this and successive issues are intended to give members who were not present a general idea of the proceedings.

SECTIONS OF MEDICINE AND SURGERY

Wednesday, July 22nd

TREATMENT OF SEPTICAEMIA

A joint discussion on the treatment of septicaemia was held by the Sections of Medicine and Surgery, with Dr. R. A. YOUNG, President of the Section of Medicine, in the chair.

Sir THOMAS HORDER, in opening the discussion, dealt first with the difficulties in defining septicaemia; he excluded those cases where the bacteriaemia was merely a temporary and not a fundamental factor, but pointed out that even in septicaemia the bacteria might leave the circulation or be undemonstrable by ordinary methods. The great problem of septicaemia centred about the general infection of the body by the *Streptococcus* and *Staphylococcus aureus*. Reviewing the treatment of septicaemia, he said that the earliest effort lay in the direction of expectant methods, which aimed at getting control of the disease rather than at "curing" it, and which should be exploited to the full and as early as possible. Institutional treatment was far better than home treatment; rest, fresh air, abundant water, sun, alkali and glucose to combat acidosis, haematinic drugs, nucleic acid and other leucocytic stimulants, and hydrotherapy were the chief constituents of the expectant method. Proper sleep and relief from pain must be secured. The arrival of immunology led to bacteriotherapy: first serum, then vaccines, sensitized vaccines, and immuno-transfusions. Bactericidal serums had been disappointing, but the advent of "antitoxic serum" offered hope. Antigen therapy had been more disappointing still, but sensitized vaccines, perhaps, still had their place. Immuno-transfusions, after ten years of trial, had little left to their credit. Then came a swing back of the pendulum to chemotherapy. Chlorine derivatives were at first popular, but these gave way to aniline dyes and mercury. Mercurochrome was now the most popular, but it had certain dangers—for example, a tendency to produce thrombosis and possible damage to the kidneys. Blood transfusions were useful at a later stage, but it was possible that some of the reputed benefits of this form of treatment might really be due to a form of "protein shock." Chemical shock he left to those who understood the teaching upon which it was based. With regard to surgery, he looked upon close co-operation between physician and surgeon as essential, especially in the earliest stages if the primary focus was known. In the later stages a thorough survey must be made almost daily for metastases; these were to be dealt with preferably by aspiration. In general, the individual case must be studied; expectant measures were to be mobilized at the earliest moment; and although all the therapeutic eggs must not be put in one basket, the patient must not be flogged with too many treatments.

Professor D. P. D. WILKIE (Edinburgh) divided cases of septicaemia into three groups. (1) Cases following accidental (especially punctured) wounds—here he asked for restraint in using the knife, for many lives had been lost by premature surgery. Passive venous congestion by Bier's method should be applied from the earliest moment, and anti-streptococcal serum should be given freely and early. (2) Following idiopathic infections—for example, osteomyelitis, or deep cellulitis. Here surgery might be imperative, because rigid walls prevented the deployment of natural resistant forces, and incision permitted expansion and the entry of protective elements. In general, he looked upon the administration of anti-streptococcal serum as of the first importance in raising the patient's powers of resistance. It must be given in the very earliest stages, before cellular damage had occurred, and must be given in adequate amount (60 c.cm. repeated daily). Copious quantities of fluid must be given by mouth, by rectum, or subcutaneously if necessary. With the fluid, alkalis and glucose were to be given freely. Vaccines he had found of no value, and immuno-transfusion had only been followed by any benefit when the patient was weak and anaemic. (3) Cases following operation in infected areas, especially those on the lower bowel. In these cases it was his custom to immunize by giving vaccines of *B. coli* and streptococcus before operation, and injections of nucleic acid.

Dr. R. A. O'BRIEN said that the serum of horses injected with *Streptococcus viridans* from cases of subacute endocarditis had not been effective. Reports on the use of antitoxin to *Streptococcus haemolyticus* varied from "dramatic cure" to "no effect." The observations of Okell and Parish explained this discrepancy. Toxin was lethal to rabbits, but antitoxin gave complete protection, and the rabbits survived in good health. Living cultures also killed rabbits, and antitoxin or anti-bacterial serum gave protection; but in this case the protected rabbits a fortnight later suffered from arthritis and other metastases—in other words, the antitoxin neutralized the toxic attack of the streptococcus, but not the pyogenic attack. Antitoxin should therefore be given at once in the treatment of septicaemia, and in large doses intravenously. Clinical reports on the newer staphylococcus antitoxin were as yet few, but were highly encouraging.

Sir WILLIAM WHEELER (Dublin) said that when the primary focus could be found and adequately dealt with the prognosis was good. He emphasized the danger in too early intervention, and especially in certain situations, such as carbuncles about the lip. He also warned against the danger in operating on prostate cases which had been previously treated with radiotherapy. Prophylactic measures should include the exclusion of infection by carriers. When no focus could be found and blood culture was positive he put the greatest faith in anti-streptococcal serum. He had never observed any benefit from chemotherapy, but stressed the need for quantities of fluid, with glucose and open-air treatment.

Mr. N. E. WATERFIELD related a personal experience after a punctured wound, and spoke of the relief given by incision.

Dr. R. KELSON FORD (London) pointed out that bacteriaemia might be latent and pass into septicaemia, and that this would occur when a suitable area of tissue of lowered resistance was provided—for example, tuberculosis of bone, osteomyelitis. Successful treatment of the first manifest focus did not necessarily imply cure of blood infection. With regard to prevention, he had found dietetic measures with vitamins, as suggested by Mellanby, of great advantage

Dr. SUTHERLAND gave his experience in treating a large number of institutional cases—namely, puerperal septicaemia and post-scarlatinal infection—and he strongly advocated the use of the milder salts of arsenic—for example, metarsinobilol in very small doses—given intramuscularly, so that absorption was slow. Colonel TOWNSEND (India) said that in dealing with large numbers of cases in India he had found no benefit from the use of mercurochrome or intravenous acriflavine. Dr. FLORENCE STONEY advised the use of zinc ionization or surgical diathermy, and medical diathermy to induce leucocytic activity. Mr. G. H. STEELE (Guildford) related two cases—one of staphylococcal and one of streptococcal blood infection—which had given a dramatic response to blood transfusion. Mr. V. H. HUDSON stressed the advantages of giving vitamins in the expectant treatment. He advised delay in using the knife, and related one case where the post-mortem examination suggested that the success which had sometimes attended Bier's treatment might be due to thrombosis of the vein preventing dilatation. Mr. C. A. JOLL pointed out that in certain cases of osteomyelitis amputation might save life. He preceded blood transfusion by blood-letting, when the patient's condition allowed it. Dr. R. A. YOUNG summed up the discussion, and Sir THOMAS HORDER replied.

SECTION OF OBSTETRICS AND GYNAECOLOGY

Wednesday, July 22nd

BREECH PRESENTATION

Mr. EARDLEY HOLLAND, President of the Section, took the chair at its first meeting. The opening paper, on foetal injuries and mortality, was read by Mr. G. F. GIBBERD (London). He pointed out that the foetal mortality rate in breech labours was usually underestimated, and he thought it a pity that a classification tending to hide the dangers had been so widely adopted. In general, a breech labour in a primipara was classified as a "complicated" case; it would be better to regard a "complicated" breech as one in which some additional obstetric abnormality was present, and under the term "uncomplicated" to include primiparae and cases with extension of the arms. With this classification the gross mortality rate for uncomplicated cases was about 30 per cent. for primiparae and about 20 per cent. for multiparae, and, all things considered, the foetal death rates of 28 per cent. and 15 per cent. respectively represented the minimum estimate of the dangers of breech labour itself. Of non-fatal accidents to the foetus, injuries to the limbs occurred in about 5 per cent. of cases. Early diagnosis of the injury was all-important, since early treatment was usually rewarded by excellent recovery. The late results of non-fatal intracranial injuries were at present uncertain, and in the absence of sufficient reliable observations the formation of definite views was not justified.

The ante-natal treatment of breech presentations was discussed by Dr. GERTRUDE DEARNLEY (London). She said that, whereas breech presentations were found very frequently up to the thirty-fourth week of pregnancy, after this time they were much less frequent, as spontaneous version occurred in a large proportion of cases. The reasons for preventing breech labour as often as possible were the higher foetal mortality and the disadvantages to the mother because of the greater risks of exhaustion and of sepsis from lacerations and damage to the pelvic floor. It was not necessary to interfere until after the thirty-fourth week. The ideal time for performing external version in a primipara was about the thirty-fifth week. She had never seen any serious complications after version, though cases of fairly severe ante-partum haemorrhage under anaesthesia had been reported. Dr. Dearnley then described the method of performing external version, emphasizing the necessity of ensuring that the presenting part was pushed out of the pelvis, most failures to turn being due to neglect of this preliminary movement. Sometimes raising the foot of the bed on chairs would accomplish this; otherwise the presenting part could be pushed up per vaginam. She recommended the application of a binder after version, especially in the case of multigravidae. If version failed it was advisable to wait for a few days, when in a number of cases it would be found that spontaneous version had occurred as a result of the manipulations. After failure to do version an *x*-ray photograph was instructive in showing exactly the position of the child. If it was revealed by *x* rays that the legs were extended, but not close to the child's head, it was possible to turn the child without risk under anaesthesia, but if, in addition, there was also extension of the child's body, it was wiser not to attempt version.

Mr. ALECK W. BOURNE (London), in an exposition of the management of breech labour, first considered the particular dangers to which the child was exposed. Such a consideration would, he thought, assist to an understanding of the reasons for the rules of management. He described the difficulties due to extended legs, extended arms, and in connexion with delivery of the head. In practice, cases might be divided into three clinical types. The first was that of a multipara who had delivered herself of the legs, body, and arms, normally and easily. Here it could be assumed that the head was flexed, and the only manipulation necessary was to grasp the feet in the right hand and lift them gently and gradually up to the mother's abdomen. The second was that of a primigravida who had been slow and "difficult." Here the head might not be fully flexed, and therefore a finger should be passed up to the chin, to feel whether it was pressed well down to the sternum. If it was flexed, delivery could be accomplished by gripping the child in such a manner as to allow some harmless traction to be made—that is, by the so-called Prague manœuvre. Great care should be taken to deliver the chin and the face slowly from under the perineum, a pause being made as soon as the mouth and nose were liberated, for the sake of both the head and the perineum. The third type was that in which it could be assumed the head was extended. Here the jaw traction method should be adopted.

The PRESIDENT (Mr. Eardley Holland), thought that the two points which would specially engage speakers were, first, the mortality, and secondly, the management of these cases.

Professor F. J. BROWNE said that Miss Dearnley had admirably described the prophylaxis of these cases. He was glad that she had emphasized the importance of version in multiparae as well as in primiparae. There was a tendency for difficulties to increase after many labours. She had been singularly fortunate in performing external version. He had not been so fortunate, and no longer regarded the operation as a minor one. Premature separation of the placenta might occur; entanglement of the cord was another possible complication. Slowing of the foetal heart, possibly due to shock, nearly always happened. Face presentation occasionally complicated external version. An *x*-ray picture before carrying out version was advisable. He agreed with Mr Gibberd about the uselessness of the hot towel; on the whole he thought it was an impediment. He thought Mr Gibberd had been singularly fortunate in regard to visceral injuries. He had never brought down a foot in the manner described by Mr Bourne, as he thought that the frank breech was a better dilator of the cervix than a half-breech. The application of forceps to the after-coming head was a most useful manœuvre.

Mr. D. W. Roy quoted statistics from the General Lying-in Hospital to show a foetal mortality of 6 per cent. in primiparae. He had had three cases of ante-partum haemorrhage after version. With regard to extended legs, his practice was not to interfere. External version should be attempted in all breech cases between the thirty-fourth and thirty-seventh weeks. The real cause of death in the majority of cases was extension of the arms and, in a lesser degree, of the head. The arms should always be sought for after birth of the umbilicus.

Dr. Fairmy (Edinburgh) said that he had analysed the figures of breech cases for three consecutive years. He was appalled at the mortality in uncomplicated cases, which, in their series in multiparae, was higher than Mr. Gibberd's. Hospital statistics were hardly a reliable criterion, as the deliveries were carried out by house-surgeons who, in the first weeks of appointment, could not be regarded as competent obstetricians. He did not agree that extension of the legs was general in primiparae; his figures suggested that it occurred in about one-third of the total number of cases. He was inclined to leave frank breeches alone unless definite difficulty was anticipated. It was most important to wait, before bringing down the arms, until the axilla had appeared. The fundus should be left severely alone when the arms were being brought down. The hot towel was of no great value, though it gave a better grip of the child. He did not believe that the child could aspirate liquor amnii and be drowned.

Dr. W. H. F. Oxley pointed out that the number of successful versions was about equal to the number of cases which were delivered as breeches. Among the unturned cases the majority were probably those with extended legs. At the East End Hospital in 1930, 219 cases were turned, and 316 went into labour as breeches. In his experience extended legs was not general in primiparae. The great difficulty to contend with was extension of the limbs. Turning had not reduced the death rate; rather, it had tended to increase it. There was no evidence that the proportion of successful versions was going up. If the training schools were not successful in turning all cases, was it likely that greater success would be obtained elsewhere? He thought that attention should be directed to perfecting their methods of delivering breech cases. He had recorded 316 cases with only 4 deaths, and a further 65 cases with only 1 death. All cases were attended by a midwife, and the doctor was not called until the os was three-fifths dilated; therefore a team of three—anaesthetist, obstetrician, and midwife—was necessary. Forceps were ready boiled. The hand was then introduced, and gently insinuated past the breech; the legs were brought down outside the vulva, care being taken that the cord did not descend. The arms were almost always folded across the child's chest. They were felt for and brought down. Extension of the arms was almost always due to traction on the body. The head should be pushed through the brim by pressure by the midwife.

Mr. Stacey (Sheffield) disagreed with all previous speakers about the classification; all cases with extended limbs were, he thought, complicated cases. A good deal could be done by Potter's method of ironing out the perineum. He advocated bilateral episiotomy after the legs had been brought down. Forceps to the after-coming head was of great assistance in increasing flexion of the head. In the elderly primigravida Caesarean section should be considered, especially when the limbs were extended.

Dr. Murray put forward the view of an experienced general practitioner. He urged that having a team or sending for a consultant was not practical politics. Much of what had been advocated savoured of meddlesome midwifery. Nature should not be interfered with. What had been said might be all right if there was going to be a specialized service.

Professor Dawson (Otago) said that he had been engaged for many years in teaching abroad, in Australia and New Zealand. Errors persisted in the textbooks, and the sooner they incorporated modern teaching the better. He most emphatically disagreed that, because a woman had had no difficulty in previous pregnancies, therefore no difficulty need be anticipated in later pregnancies. He confirmed the uselessness of the hot towel; it prevented the child from breathing. It was of the greatest importance to teach the student to prepare his equipment as a routine. He thought bilateral episiotomy was a mistake, except in occasional cases.

Dr. Pollock said that he would henceforward be less eager to use a hot towel. In some cases he thought it was extremely difficult to diagnose breech presentation. Dr. Moir had seen one or two unfortunate cases of foetal death *in utero* after version had been performed under anaesthesia. Too deep and too prolonged anaesthesia was a great danger to the foetus. Forceps gave complete control over the after-coming head, for the easy extraction of which he advocated a single episiotomy.

Mr. Eardley Holland said that he had made a careful study of breech labour for a number of years. He commented on the extraordinary divergence of opinion on mortality. He had always maintained that the great difference between the hospitals and other institutions was due to the staffing of the hospitals by comparatively junior resident officers. The death of the foetus occurred at the vaginal outlet. In 75 per cent. of cases there was evidence of pressure on the head. He agreed that episiotomy was of the greatest assistance. It was almost his universal practice to do this when the buttocks were distending the perineum. He advocated delivery with the woman on her back. He totally disagreed with Mr. Bourne about bringing down the legs. Extended legs should only be brought down if they were causing a delay of from fifteen to twenty minutes. Getting down the arms was a complicated process, entailing six or seven movements. External version should be done in every case. The anaesthetic was a real danger to the baby. Mr. Gibberd, in reply, thanked Dr. Oxley in particular, and Mr. Roy also, for his figures. Dr. Dearnley thought that the cord might be wrapped round the body by spontaneous version as well as by external version. She agreed that the anaesthetic was a danger, and had rarely found one necessary. Mr. Bourne thought that obstetricians did not see a large number of normal cases. He never had an anaesthetic given in any circumstances when doing a version.

SECTION OF DISEASES OF CHILDREN

Wednesday, July 22nd

Jaundice in Childhood

With the President, Dr. H. C. Cameron, in the chair, Dr. A. C. Hampson opened the discussion on jaundice in childhood. Taking excess of bilirubin in the blood as a measure of the condition under review, he briefly summarized modern opinions on the mechanism of production of jaundice. With regard to the type of jaundice undoubtedly due to toxins, he emphasized that morbid processes were seldom due to one factor only, and besides the question of the "seed" and the "soil" there were often factors which might be called "fertilizers." It had been observed, for example, that poisons which exerted their toxic effect on the liver usually showed a maximal effect in the infant. Dealing next with jaundice of the newly born, the speaker pointed out that probably all infants at birth showed an excess of bilirubin in the blood; when obvious jaundice appeared it was usually not visible before

the second day, and the condition was likely to be more marked in premature babies. With regard to the causation of this condition, Dr. Hampson said that his own work showed there was a very high value for bilirubin in the umbilical vein at birth, and it was, in his opinion, possible that in the case of the newborn infant the jaundice was due to changes occurring during parturition. It was suggested that this was connected with a comparatively slow assumption of its new duties on the part of the liver, but further observations went to show that in many ways the jaundice of the newly born resembled haemolytic anaemia. Biochemical observations on the reaction of the plasma and the red blood cells confirmed this, and suggested that a haemolytic element in such forms of jaundice must certainly be considered. This benign form of icterus had similarities with the so-called icterus gravis neonatorum, and, in his opinion, too many lives were still being lost from this severe form of jaundice, which was open to successful treatment. Acting on the haemolytic theory for the physiological form of jaundice, and on other findings, he had had very good results in the grave forms with the injection of human serum in doses of 15 c.cm. daily for three or four days, combined with mercurial inunction. Turning next to congenital obliteration of the bile ducts, the speaker discussed the various theories about this condition, summing them up under the heads of developmental narrowing and maternal toxins. Here, also, he recommended the use of mercurial ointment. Syphilitic and toxic jaundice were briefly dismissed, and Dr. Hampson dealt then with epidemic infective or catarrhal jaundice. He stressed the fact that the real condition present was a hepatitis, which might produce a toxic cirrhosis. He spoke of the infectious nature of the disease, which had a definite incubation period, and in more serious cases he recommended intravenous glucose, together with small doses of insulin, as a good form of treatment. In conclusion, he briefly considered a number of other conditions in childhood with which jaundice is associated.

Dr. J. C. SPENCE (Newcastle), speaking of catarrhal jaundice in children, said that the modern view of this as a form of hepatitis was a useful one, and emphasized that, although the causal organism was unknown, it was certainly not the leptospira discovered in association with jaundice in the war. From the clinical aspect, he said, the epidemics of catarrhal jaundice did not differ from the jaundice of campaigns, and, like such cases, also showed the occurrence of acute or subacute necrosis of the liver, in some cases terminating fatally. This supported the view that hepatitis was the real lesion present, which received further confirmation from the fact that liver tolerance tests showed a diminished liver function, most marked in the early stages of the disease. Mentioning the importance of treating catarrhal jaundice, Dr. Spence said that the giving of easily assimilable carbohydrate was of great value. Turning next to the question of cholaemia, the speaker described the term as a bad one, but worth retaining, and then described a typical example of the condition in a young boy, where the symptoms at first strongly suggested meningitis. There was a restless state, with curious attacks of shrieking; the right plantar response was extensor. Convulsive attacks, with opisthotonos, occurred, and nervous symptoms predominated throughout, jaundice only being observed during the last twenty-four hours. He suggested that a study of cholaemia might throw some light on the obscure nervous symptoms of ordinary catarrhal jaundice. With regard to jaundice in the young baby, he emphasized that syphilis was nowadays a rare cause of jaundice; he thought that a relatively common type of case was severe jaundice in the newly born, with a large liver and spleen, where recovery was possible, but might be associated with cerebral diplegia. The various forms of jaundice he had discussed were comparatively rare.

Dr. W. W. PAYNE dealt first with the fragility of the red blood cells in jaundice and other conditions. He employed a naked-eye test, where washed red cells were placed in various concentrations of saline. The normal range showed complete haemolysis between 0.30 and 0.36 per cent. saline, with the range for a trace of haemolysis lying between 0.36 and 0.42 per cent. In jaundice and other conditions where the liver was diseased the cells showed a slight tendency to an increased resistance, and it could be taken as a rule that, unless another diagnosis could be made with certainty, any patient having an abnormally high fragility and a positive van den Bergh reaction was suffering from acholuric jaundice. The degree of fragility was not constant in this condition, and after operation for removal of the spleen in four cases, two only showed a normal fragility; it was possible that in the others an accessory spleen prevented complete return to normality. In the second part of his paper Dr. Payne dealt with liver-function tests. The value of such tests was twofold—either as tests of the function of the liver itself, in given cases of liver disease, or as tests of the function of the liver in other diseases. He gave a brief comparison of the various tests in use, and gave an account of a series of children with asthma, investigated with Dr. Bray, in which the effect of adrenaline injection on the blood sugar and the rise of the blood sugar after the giving of levulose by the mouth had been observed, with seemingly contradictory results in many instances.

Dr. H. H. CHODAK GREGORY spoke about congenital atresia of the bile ducts, bringing forward fresh evidence to support the theory of developmental anomaly. In a case under her observation which came to necropsy, the external bile ducts, though present, were flat and empty, while in the liver substance there appeared to be scarcely any peri-portal bile ducts, although bile capillaries were in full evidence and gorged with bile. In such a case it was the intermediate bile passages which had failed to develop. Discussing other theories of the origin of congenital obstruction of the bile ducts, she pointed out that, although the one which attributed the condition to maternal toxaemia offered most hope in treatment, the evidence was more in favour of a developmental error.

The PRESIDENT emphasized the value of Dr. Hampson's work in discovering the value of human serum in the treatment of the tragic cases of familial jaundice in the newly born. He referred to the similarity between the child with night terrors and the terror-stricken condition in cholaemia, and said that it was by seeing a case of the latter that he was led to try the effect of glucose in children with night terrors. He was interested in the possibility of treating congenital obliteration of the bile ducts by surgical means, but had been disappointed with what he had observed in some cases. Dr. HELEN MACKAY asked if citrated whole blood was as good as serum in the treatment of grave familial cases of jaundice in the newborn. She said that the condition was probably commoner than was usually supposed, and emphasized that so many cases of jaundice in the young baby seemed to be of composite origin.

Dr. ALAN MONCRIEFF asked why haemolysis occurred in young babies (if Dr. Hampson's views were correct), and if it had anything to do with the blood group of the child differing from that of the mother. He described a family where two children had sore throats followed by catarrhal jaundice, while the third child also had a sore throat but developed appendicitis, which suggested that the naso-pharynx was the portal of entry in epidemics of catarrhal jaundice. He mentioned the value of drainage of the gall-bladder in cases of this condition where the jaundice was

unduly prolonged. Mr. E. H. RAINEY (Eastbourne) pointed out that premature babies showed a greater tendency to the so-called physiological jaundice than babies born at full-term, but, apart from this form, he thought the other types of jaundice in the young child were very rare. He questioned the rationale of draining the gall-bladder or attempting any anastomosis in cases of congenital obliteration, as it was likely that the obstruction lay above the origin of the cystic duct. Dr. C. F. HARRIS spoke about the theory of the cause of physiological jaundice, which ascribed the greatly increased number of red blood cells in the foetal blood to a difficulty in obtaining oxygen. When this disappeared with the establishment of pulmonary ventilation at birth, the child had no longer any need for this excess of red cells, which were destroyed, producing the jaundice.

Dr. ELIZABETH GUNN (New Zealand) described a small epidemic of catarrhal jaundice occurring in a children's camp, where the first symptom was slight sore throat. Dr. J. HUTSON (Barbados) spoke of the very high incidence of all forms of jaundice in children in Barbados. Four out of five babies showed jaundice within forty-eight hours of birth. He had also seen many epidemics of catarrhal jaundice which was probably toxic in origin.

SECTION OF PUBLIC HEALTH (INCLUDING TUBERCULOSIS AND OCCUPATIONAL DISEASES)

Wednesday, July 22nd

SOME RECENT POLICIES REGARDING PARTICULAR DISEASES

Sir GEORGE BUCHANAN, President of the Section, opened the proceedings with an address on recent policies in connexion with particular diseases. As an example of the policy of complete exclusion of an infective disease from this country he cited the case of psittacosis, commenting humorously on the surprising need for parrots which became manifest as soon as the importation of these birds was limited. The really difficult point was the determination of the time when they could be readmitted. He then considered the risk of spreading yellow fever in the case of laboratory workers, and also in the more serious contingency of transmission of the infected mosquitos by aircraft. Medical requirements might put some obstacles in the way of aviation in tropical countries. National and international policies on the prevention of malaria were then reviewed. It was possible that drugs more potent prophylactically than quinine would soon be available. Isolation hospitals were becoming more intimately associated with clinical and bacteriological research. Their scope was widening, and they would fulfil an increasingly valuable purpose as centres for the collecting of information. The earlier policy of segregating healthy "carriers" was now less favourably considered, in view of the embarrassment caused to the community, and of the slight amount of benefit obtained. It was too early yet to state that in this country active immunization was becoming the basis of a new public health policy, but distinct tendencies pointed in this direction. In diphtheria and scarlet fever it was possible that simple immunization could be effected by a few injections with no resulting disability.

Sir George Buchanan, discussing the question of vaccination and small-pox, emphasized the need of mass vaccination, and illustrated his contentions by the cases of Italy since 1923, of the French African colonies, the Dutch East Indies, India, and of Russia. Great Britain was profiting from these measures in that the risk of importation of small-pox was thereby lessened. Mass anti-cholera vaccination was playing an increasing part in the East, notably in India in connexion with pilgrims, and in China. In Shanghai last year more than half a million persons had been inoculated on the first appearance of cholera. He then gave a few examples of the communal detection and control of disease. Special attention was being directed to the prevention of acute rheumatism in children; local schemes comprised three factors—namely, ascertainment, supervision, and treatment. Elasticity was an essential characteristic of such local schemes if they were to be successful. Both the State and the municipal authorities were beginning to concentrate against cancer in this country and also abroad—notably in France, Italy, Spain, and the United States. Classification of the patients was furthered, and an educational policy was being pushed; but it was as yet too early for the instituting of a national scheme. Local effort and the co-ordination of all persons and organizations interested were improving. While national uniformity was desirable and standardization often necessary, communities, large and small, should continue to work out and apply new policies of their own; being ready to reconsider these when the time came.

INDUSTRIAL PROBLEMS FROM THE STANDPOINT OF GENERAL PRACTICE

Dr. L. P. LOCKHART (Nottingham) opened a discussion on industrial problems from the standpoint of general practice in a paper which is published in full this week at page 179.

Sir GEORGE BUCHANAN congratulated Dr. Lockhart on introducing so novel an outlook into the subject. Samuel Butler in *Erewhon* had somewhat anticipated him in contrasting the machine and the man. Dr. Lockhart might have some difficulty at first in recasting the present Factory Acts on these principles.

Mr. ERNEST GRIFFITHS, speaking as a surgeon, dealt with the simple fracture in the workman, as a single example of a problem arising out of industrial injuries. The direct causes of failure of the present methods of treatment were: (1) pain; (2) muscular and joint stiffness; (3) muscular weakness and wasting; (4) inco-ordination of muscular movement; and (5) circulatory disturbances. A special fracture hospital was necessary (or a special fracture department in a general hospital), where the fracture could be set immediately under general anaesthesia, and under the special supervision of the director. Adequate immobilization should follow, but this should be associated with full movements of the unaffected parts of the limb concerned, so that, when the plaster was removed, only a few days would be necessary for the restoration of full function. Massage must be used more intelligently; it was at present a menace to the industrial worker, who needed more encouragement to use his limb. Supervision by the patient's own medical attendant should include encouragement to resume work as soon as possible. In the question of compensation in injury, malingering was relatively very rare; but the system of lump-sum settlement operated injuriously in many cases. The capital value attached to the disability made it difficult to treat, and the sooner this matter could be settled the more quickly would healing progress. Getting fit was a whole-time job.

Dr. W. G. WILLOUGHBY, President of the Association, commended to the meeting the *x*-ray photographs of industrial diseases in the exhibition. They had been specially brought over, and were probably unique.

Dr. SYBIL G. OVERTON (Medical Inspector of Factories) urged the importance of recognizing, in workers, the origin of the disease, in the elucidation of which the general practitioner should play a more prominent part. As an aid to this the recognition of trade stigmata was very valuable. In regard to the fear factor some recent work by the Industrial Health Research Board had adduced evidence that the sickness rates were high in those forms of work where the fear factor could be eliminated.

Dr. L. G. IRVINE (Johannesburg) thought that Dr. Lockhart had skated rather lightly over the psychical effects of unemployment. Work-shyness was rather apparent, and might be associated with a higher sickness incidence. Unemployment insurance had the tendency to accentuate natural human indolence, and might increase invalidity.

Dr. W. F. DEARDEN (Manchester) agreed that the health problems of industry were more associated with general practice than was admitted to-day, but he thought that, though every general practitioner was a psychologist, the extended aspect of the question as presented by Dr. Lockhart was rather more than he would like to take up. He believed that it was from those holding similar appointments to that of Dr. Lockhart that the investigation required would be most successfully carried out. He added, however, that in his view the general practitioners should know more about industrial problems and diseases than was the case, and referred to the principles laid down in this connexion over 200 years ago by Ramazzini. There were so many Government regulations on the subject that this knowledge had now become a necessity.

Dr. LOCKHART agreed that malingering was rare. He had seen ringworm fungus in two cases diagnosed and treated as bakers' dermatitis, so increased diagnostic care was necessary. He cited an incident in the printing industry, where the introduction of a new machine had thrown many men out of work. Fear of losing work in such circumstances was almost inevitable. It was not the dole which was upsetting man. Naturally indolent, he had, nevertheless, a biological need of work, which could not be satisfied by payment. Dr. Lockhart quoted a case of generalized eczema which invariably recurred as soon as the patient was discharged fit for work. Other fear causes were enteroptosis, functional and imaginary cardiac irregularities, and neuralgias. Psychogenic causes were more prevalent than was generally realized.

SILICOSIS IN INDUSTRY IN SOUTH AFRICA

Dr. L. G. IRVINE (Johannesburg) maintained that the risk of silicosis in South Africa was mainly limited to gold mining. The subject was important in view of the increased disability coincident with the growth of this industry. Free silica existed to the extent of 70 to 80 per cent. in gold ore, and numerous persons were concerned in dealing with it. He described the development of the industry and the progress made in detecting and preventing silicosis. Two methods of prevention were used; in one water was employed, and in the other avoided. Blasting could be timed so that persons could be out of the dust-laden atmosphere. Great progress had been made by combining both methods; but cases of silicosis were still occurring. The provision of ample ventilation was of primary importance; had this been realized thirty years ago most troubles could have been prevented. When water methods were first introduced it was thought that the problem had been solved; but a very fine dust still remained, and was carried with tubercle bacilli into the lungs by the water-laden air. Medical measures were centred in the work of the Miners' Medical Bureau, a highly organized and well-equipped organization, which had been established in 1916. All new recruits to the industry were examined, and men with tuberculosis or other diseases were excluded. Thus the "new Rand miners" so examined were of good physique, and were gradually replacing the old-time workers. Awards were granted for those who became ill. The Bureau examined men at work, decided claims, and assessed benefits to be granted. Post-mortem examinations were made. All natives were weighed every six weeks, and carefully examined if there was any loss. All falling sick had their chests examined as a routine procedure. About 140,000 native miners came under these regulations. Dr. Irvine gave details of the number of cases dealt with, showing how the disease had been reduced. During the past ten years there had been a progressive but not uninterrupted decline; this was illustrated by a graph which showed the percentage attack rates at different periods. The ultimate outlook was now more encouraging, and further decline in the incidence of disease was possible. Three classes were recognized—namely, silicosis, silicosis with tuberculosis, and pure tuberculosis; the second class was now described as "cases of silicosis of *infective* type." Silicosis and tuberculosis were distinct pathologically, though similar as regards symptoms and histology. The Bureau had now been able to define diagnostic standards. A properly taken radiograph was a trustworthy, though not the sole, criterion, and could indicate the extent of the silicotic process. The only specific radiographic sign was a discrete mottling which appeared first in the upper half of one or both lung fields, but later became more generalized. It resembled somewhat the branches of a leafless tree. In early cases of silicosis there was no impairment of the general health, apart from slight respiratory difficulty and a liability to recurrent colds. When associated with tuberculosis the silicotic progress was modified, a massive fibroid consolidation often resulting which rendered diagnosis more difficult, and might show periods of arrest. Such a consolidation, however, did not always imply tuberculous complication.

POST-MORTEM EXAMINATIONS

The President, Professor E. B. CATHCART, took the chair.

Dr. EDWARD F. HOARE, Coroner for the Lewes District of East Sussex, in opening the discussion on post-mortems, their object and performance, said that there were three groups of practitioners: (*a*) those who had no wish to do coroners' post-mortems; (*b*) those who wished to do them as a protest against the increasing tendency to limit private practice; and (*c*) a small group who were eager to do them. All three groups generally admitted that it was years since they last did a post-mortem. A coroner could only direct a post-mortem in suspected cases of sudden, violent, or unnatural death, and there must be reasonable grounds for suspicion; he could not hold either a post-mortem or an inquest merely at his will. About twenty thousand post-mortems a year were directed by coroners, and under the Act of 1887 they might summon "any legally qualified medical practitioner who attended the deceased at his death or during his last illness," or if not so attended, "any legally qualified medical practitioner who is at the time in actual practice in or near the place where the death happened." But the newer Act (1926) adds: "He may further request any other legally qualified medical practitioner to make a post-mortem examination and report" The compellability depends on practice in the place; other practitioners, including specialists, may be "requested," which request could be refused.

The purpose of the post-mortem examination was only incidentally to ascertain the cause of death, and to a coroner was only of interest if it shed light on the question of "how the deceased came by his death." Until it was realized that the medical interest lay in the pathological cause of death, whereas the legal interest was in the manner thereof, there would be conflict and misunderstanding between doctors and coroners. A disease of the heart might suggest a cause of death, but without examination of the brain or kidney, how was a granular kidney or a cerebral haemorrhage to be excluded as a cause? And

if the latter were a cause, the question of its origin—whether by disease, accident, or assault—would at once arise. Yet frequently the brain was not examined if a possible prior cause was found. Dr. Hoare said that his own scheme was to employ pathologists when possible, police surgeons as an alternative, and odd practitioners in occasional cases. He submitted that the legal fiction of equality of practitioners applied only to legal status and their potential abilities. Their particular superiority in any branch depended on opportunity and experience, and only implied a particular, and not a general, superiority. He maintained that a trained pathologist was superior to either surgical or medical consultant, or to a general practitioner, for this particular work.

Dr. G. Roche Lynch said that he fully concurred with Dr. Hoare that the conduct of the post-mortem examination and the proper interpretation of results could only be satisfactorily achieved by those who had made a special study of pathology, and that accuracy and reliable evidence was not only necessary in the coroner's court, but absolutely essential if justice was to be administered in the higher courts. The following case, though not criminal, was illustrative. A couple were found dead in their flat; suicide was presumed. At necropsy the doctor was satisfied that cyanide was the cause of death (mainly because of bright colour of blood and the mistaking of post-mortem digestion of stomach for corrosive poison). Coroner decided on an analysis; CO was found, and it was subsequently decided that death was accidental, due to faulty gas heating apparatus. This was not all, for the executors sued the makers of the gas apparatus in the High Court, and got substantial damages. Speaking as a toxicologist, he would like to add that their knowledge of the action and effects of poisons was still very imperfect, in many instances they had to rely on recorded cases which occurred fifty or more years ago. If any real advance was to be made they must have not only material for investigation, but also accurate observation and inference. Many other countries had made provision for the investigation of medico-legal cases by trained observers, but in this country they were slow to follow.

Dr. H. W. Webber (Plymouth) said that it would be most regrettable if the proposal to centralize all post-mortem work in every large city and in county areas was carried out. Midwifery was handed over to the nurse midwife, surgery to the hospital surgeon, dispensing was done by the chemist, and now post-mortems were to be done by specialists. If a general practitioner was a general practitioner in deed he would undertake all branches of practice, calling in the specialist for the more difficult cases. The argument had been advanced that the general practitioner had not sufficient knowledge to do justice to the work. He suggested that in every city and large district a mortuary should be established in which all bodies requiring it could be examined by the practitioner. Dr. Webber said that, in the discussion in the *Journal* last year, he wrote, "Let us do our own work and face our responsibilities." He still held strongly to that opinion.

Dr. A. J. Hawes (Wisbech) said that, although a general practitioner, he held the not very popular view that most general practitioners should not do post-mortems, because they could not be expected to do them properly. It seemed right that the proper person to do a certain task was the one who could do it best, and that the general practitioner should cease to do those things that could be better done by others. Specialism had certainly captured some of their hunting-grounds, and they took care that everybody heard about it; but they did not talk about the rich new pastures which every advance in knowledge had opened up for them. The general practitioner was not losing ground; he was only shifting his ground.

Colonel H. A. Smith (Hawkhurst) believed that special work should be carried out by those specially trained or experienced in it. From the first post-mortem examination he made he learnt that the examination itself should be complete and thorough, and that the medical man should be prepared to answer any questions which might be put to him at the inquiry. Before death, where there was any suspicion of poison, he strongly urged the examination of the urine and the removal of the patient from his immediate surroundings.

Professor A. Murray Drennan (Belfast) said that in his experience practitioners did not want to do post-mortems, as they were a great deal more trouble than they were worth. One never knew when a post-mortem might require further bacteriological, chemical, or histological investigation, on the result of which might depend the life and liberty of some individual. The practitioner had no facilities for this kind of work. Even the pathologist as such might not be an ideal medical jurist; he needed special experience of medico-legal matters—such as points of identification, signs of putrefaction in different media, special injuries occurring in violent death, and so on. He had seen quite good post-mortems done by practitioners, who could not, however, become expert, even after a course of reading and short attendance at some large centre, as suggested by Dr. Webber, so that, as far as possible, trained pathologists should do this work. Dr. P. G. Stevenson Davis said that, if general practitioners were to be divorced from pathology by the employment of pathologists at all post-mortems, they should at least be provided by right (and not as a favour) with a fairly detailed report of the post-mortem findings. Without this they were quite unable to check the diagnosis made during life, or to refute tales of the discoveries made post mortem. A practitioner was often quite unable to attend the post-mortem personally because of his work.

Dr. W. G. Barnard said that a newly qualified practitioner had only the vaguest idea of how to make a post-mortem examination, and practically no experience in interpreting his findings. He might do no post-mortems for years in his practice, so that, however keen he might be, it was quite impossible for him to be a competent person in this work. With regard to the suggestion of Dr. Davis, he felt sure that no coroner would object to the presence of the practitioner at the post-mortem examination, and that pathologists would welcome it. Dr. A. G. Shera (Eastbourne) thought it would be an advantage if the clinician could be paid a fee for a full history of the case, or, if the clinician's presence were made compulsory at the post-mortem examination, a fee should also be paid. Dr. H. W. C. Vines said that a factor in the difficulties general practitioners had in performing post-mortems was the inadequacy of their training in the subject. Dr. E. H. Hunt drew attention to the difficulties found in out-of-the-way parts of the world by practitioners who had had little experience and were suddenly called on to do post-mortems. He received no sympathy if he confessed that he had been unable to find a cause of death. Dr. C. W. Cunnington suggested that, when a pathologist was directed by the coroner to make an examination, the general practitioner should be invited to attend if he desired to do so.

Dr. Hoare, in his reply, said that there were not enough post-mortems to give a general practitioner sufficient experience or training as a pathologist, and the expense of paying both a pathologist and a practitioner would prohibit fees being paid to both. He had, however, persuaded his council to pay 10s. 6d. for letters from clinicians when these materially assisted the inquiry.

SECTION OF NEUROLOGY AND PSYCHOLOGICAL MEDICINE

Wednesday July 22nd

CEREBRAL HAEMORRHAGE

The first day's proceedings were devoted to a discussion on cerebral haemorrhage due to causes other than arterio sclerosis The President, Sir JAMES PURVES STEWART, was in the chair, and the discussion was opened by Dr JAMES COLLIER After a brief historical review, the opener dealt with the causes of the type of haemorrhage under discussion These included injuries during birth or following trivial concussion, haemorrhagic pachy meningitis, encephalitis, poliomyelitis, tuberculous *meningitis*, *sinus thrombosis*, abnormal blood states, such as leukaemia, anthrax infection, neoplasms, aneurysm—infective in ulcerative endocarditis, etc, aneurysms occurring in coarctation of the aorta and in polyarteritis acuta nodosa, congenital aneurysms, and syphilitic aneurysms Of these causes Dr Collier con sidered the three most important to be (1) encephalitis, (2) *neoplasms*, and (3) aneurysms Many cases of encephalitis lethargica, confirmed by histological examina tion, have been complicated by subarachnoid or cerebral haemorrhages He considered encephalitis also of interest in connexion with the subject, as many cases of subdural, of subarachnoid, and of cerebral haemorrhage from rup tured aneurysms had been recorded in which the clinical picture was hardly distinguishable from that of encephal itis lethargica Soft neoplasms were important causes of cerebral haemorrhage, which might occur before the appearance of any local or general signs The opener dealt especially with haemorrhages occurring from the berry like and often multiple aneurysms which have been called congenital Such lesions were the commonest cause of cerebral haemorrhage in younger subjects They were commoner than was generally supposed, and might exist without giving rise to symptoms In cases proving fatal from haemorrhage it was sometimes not possible to demon strate the aneurysm post mortem, as it was often em bedded and lost in blood clot Although aneurysms at the base of the brain were frequent, they were not so rare on the convexities of the cerebral hemispheres as had been supposed For subarachnoid haemorrhage from such aneurysms Dr Collier emphasized that his practice was always to drain freely the subarachnoid space by means of repeated lumbar puncture as long as the symptoms of increased intracranial pressure persisted He showed an admirable series of lantern slides of specimens of intra cranial aneurysms

Professor A J HALL (Sheffield) limited his remarks to the subject of subarachnoid haemorrhage The occur rence of massive albuminuria in this condition had to be borne in mind, in such cases at post mortem examina tion the kidneys might be found normal Korsakow s syndrome sometimes occurred as a sequel, and lasted for a considerable time Recovery from this condition was the rule From time to time symptoms might occur indicating leakage from an aneurysm, finally a blow or sudden exertion might determine a fatal haemorrhage—A medico legal aspect of this was important

Dr W J ADIE referred to the association of cerebral aneurysms with polycystic disease of the kidneys Intra cranial aneurysms might give rise to symptoms resembling those of migraine, especially headache and vomiting The symptoms of aneurysm differed from those of migraine in that the hemicrania was always on the same side and the visual aura did not reach a climax in a gradual manner but developed more suddenly He considered that aneurysmal rupture had a seasonal incidence and that it was more frequent during the summer months The condition known as ophthalmoplegic migraine must always give rise to a suspicion that the symptoms were really due to the presence of a leaking basal aneurysm

Mr HUGH CAIRNS discussed the surgical treatment of intracranial haemorrhage, quoting cases both of subdural and intracerebral haemorrhage that had been treated successfully by operation He emphasized the importance of small bilateral subdural explorations under local anaesthesia in every case in which subdural haematoma was suspected At the present time accurate diagnosis of this condition was not always possible by clinical methods alone A case was cited to illustrate the good results that could be obtained from removal of large blood clots from within the brain itself

Dr J PURDON MARTIN mentioned a case of sub-arachnoid haemorrhage from an intracranial basal aneurysm in which the cerebro spinal fluid withdrawn by lumbar puncture on the fifth day of illness was free from blood This was a most unusual occurrence Sub-dural haemorrhage as a sequel to a head injury might be very widespread without any fracture of the cranial bones, such a condition might be fatal or give rise to chronic subdural haematoma The localizing signs of the latter were often vague and deceptive In elderly subjects the injury giving rise to a subdural haematoma might often be of a trivial nature even jerking of the head might cause such a haemorrhage Following the injury there was often a latent period of weeks or months during which only slight or vague symptoms might be present, signs of cerebral compression developing later In some cases the extravasated blood did not clot, but appeared to undergo defibrination

Dr J G GREENFIELD limited his remarks to the so-called 'berry" aneurysms In his experience, these had been found most frequently on the arteries of young or middle aged subjects who had shown either no trace of atheroma or only small isolated plaques Abnormalities of the cerebral or systemic arterial systems had been commonly described in patients who had died from rup tured *intracranial aneurysm*, which supported the theory that malformation of vessels was the cause of these aneurysms In this connexion a most important observa tion was that of Wiley Forbes He had shown that there was primarily a defect in the muscular coat of the artery, and had demonstrated its presence not only at the point *where the aneurysm formed* but at practically every bifurcation of the cerebral vessels in these subjects Dr Greenfield had examined the cerebral arteries in five non atheromatous cases of cerebral aneurysm, and had found such a defect present in all The speaker illustrated his remarks with lantern slides showing the defects in the arterial muscular coat in several cases

Mr A A MCCONNELL (Dublin) described a case of sub dural haematoma in a man, *aged 70 in whom headache* appeared two days after jerking the head In the course of a week focal symptoms—paresis of left arm and leg—made their appearance At no time was consciousness impaired although cerebration was slow Mr ASTLEY CLAPPE (Leicester) mentioned hilarity as an early and only symptom in a case of basilar artery aneurysm at the age of 24 He quoted two further cases in which laughing of an unusual character was observed as an early symptom Dr HINDS HOWELL referred to a case of subdural haematoma in which operation was performed The patient improved for twenty four hours and then became semi conscious At necropsy a subdural [illegible] was found on the opposite side of the brain In sub arachnoid haemorrhage [illegible] might occur in addition to albuminuria [illegible] of diagnosis Following the [illegible] discussion, Dr COLLIER briefly replied

SECTION OF OTO-RHINO-LARYNGOLOGY

Wednesday, July 22nd

SORE THROATS OF OTHER THAN TONSILLAR ORIGIN

The chair was taken by Mr. W. M. MOLLISON, President of the Section. In opening the discussion Mr. BEDFORD RUSSELL deplored the tendency to consider all sore throats as due to inflammation of the tonsil. He described the type of case in which sore throats persisted after removal of tonsils, some infection eventually being found in the nose. In other cases sore throats were entirely cured by treatment of nasal sepsis without the tonsils being interfered with. Laryngitis, besides pharyngitis, was very often secondary to nasal disease. The common nasal condition was that of infection of the maxillary antrum, and persistent or recurrent inflammation of the cavity gave rise to a considerable proportion of sore throats. Transillumination was very valuable in these cases, and any infection at all should be treated by intranasal drainage and lavage. It was rarely necessary to perform the Caldwell-Luc type of operation. The ethmoidal or sphenoidal sinuses might also be the cause of sore throats, and should be treated appropriately.

Mr. J. B. HORGAN (Cork) considered that dental sepsis also caused many sore throats, especially in connexion with erupting molars. He also mentioned pharyngeal paraesthesia in women. Mr. J. F. O'MALLEY remarked that nasal obstruction, besides infection, could cause sore throats. Nasal ventilation was very important, and a healthy antrum would clear itself of infection if it had adequate ventilation. Mr. HORSFORD described a case of recurrent sore throat lasting four years after tonsillectomy, and entirely due to an infected antrum. Mr. E. D. D. DAVIS said that in some cases, when the nasal trouble had been cleared up, tonsillitis remained, but he agreed with Mr. Russell in his stand against indiscriminate tonsillectomy. Mr. TILLEY and Mr. SCOTT RIDOUT mentioned the inflamed lymphoid masses behind the posterior faucial pillars as a frequent source of sore throat.

Mr. LOWNDES YATES drew attention to the possibility of infection being kept up by some other member of the family or household.

TREATMENT OF OESOPHAGEAL CARCINOMA

Mr MUSGRAVE WOODMAN (Birmingham) opened the discussion on the treatment of malignant disease of the oesophagus. He said that the oesophagus was fixed at either end, but freely movable in the rest of its course. It had no serous coat, and there was no barrier to the spread of disease. There was a very free lymphatic drainage, and once the preliminary resistance had been overcome spread was very rapid and wide. It was difficult experimentally to produce any protective thickening of fibrous tissue around the oesophagus by irritative substances or otherwise. Radium could be applied centrally, intramurally, or peripherally. The last method across the pleural cavity was practicable, but not followed by the good results of intramural implantation of radon seeds, in which it was only possible at first to reach the upper part of the growth. Central insertion of radium could deal with the whole length of the stricture, and was applied by rubber tubular holders, which had the advantage of accommodating themselves to the oesophageal movements. Diathermy just failed because it produced no protective thickening, but it did cause much relief. Further work was needed on the dosage and screening of radium, and on the radio-sensitivity of oesophageal growths.

Mr. W. M. MOLLISON, the President, considered that diathermy was of great value in these cases, and enabled patients to swallow. Gastrostomy was also extremely useful, and rested the oesophagus. Mr. SCOTT RIDOUT said that radium caused a great regression of the growth, and he found that radon seeds were the best method of application. Preliminary gastrostomy was very helpful. Sir JAMES DUNDAS-GRANT said that after large central doses of radium there was considerable relief for a time, but later extension or necrosis through the wall of the oesophagus took place. Mr. E. D. D. DAVIS thought that with Mr. Woodman's tubes it would be possible to apply smaller doses of radium for longer periods, which was desirable; but the tubes could only be tolerated in growths of the medial portion of the oesophagus. Mr. WOODMAN, in reply, said that soft vascular growths responded best, and that large doses of radium gave rise to massive necrosis. He was not very enthusiastic about gastrostomy.

ANOMALIES OF THE UPPER JAW AND NASAL SURGERY

Mr. J. B. HORGAN (Cork) read a paper on the developmental and anatomical peculiarities of the upper jaw in relation to surgery of the nose and accessory sinuses. He mentioned the changes in the upper jaw associated with contracted arched palate—lengthening of the face, lowering of the alveolar margin, with narrower nasal passages, resulting in obstruction of the antral orifice. The floor of the antrum might be lowered, giving rise to a marked recess below the level of the floor of the nose. He considered that intranasal antrostomy was unsound, practically and theoretically. He always operated through the canine fossa, which enabled him to deal thoroughly with antral infection, polypi, etc., and which gave him a very good access to the ethmoidal region and to the sphenoidal cells. Mr. O'MALLEY said that intranasal methods gave rise to very good results. Sir JAMES DUNDAS-GRANT placed great value on the Canfield operation. Mr. TILLEY said that a mild infection could be treated intranasally, but a heavy infection with polypi usually called for more radical measures. Mr. FORSTER considered that the high-arch palate might not always be due to nasal obstruction, but was in some cases hereditary.

ASTHMA AND NASAL CONDITIONS

Sir JAMES DUNDAS-GRANT read a paper on the nasal factor in spasmodic asthma. Asthma often occurred with, but might occur without, nasal abnormalities, and abnormalities might occur without asthma. There must be other predisposing factors. These might be psychic or due to some lesion elsewhere. They might be anaphylactic or allergic, or due to faulty feeding, especially with too great a proportion of farinaceous material. Intestinal intoxication was also a very important factor. In many cases, however, there were definite nasal conditions which seemed to produce asthma, and if corrected the asthma disappeared. The commoner conditions were enlarged middle turbinal, enlarged anterior lip of the hiatus semilunaris, nasal polypi, and deflected septum. In a great many cases cure was produced by correction of these conditions; in many more considerable relief was obtained. In cases of complete failure other factors must be predominating. In young children in whom asthma persisted after removal of tonsils and adenoids it was usually found that the turbinals were enlarged, and reduction of these brought about disappearance of the asthmatic symptoms.

SECTION OF OPHTHALMOLOGY

Wednesday, July 22nd

OPHTHALMIA NEONATORUM

The chair was taken by Mr. E. E. MADDOX, who expressed his gratification at the honour done him in being elected President of the Section of the "Queen of specialties." He extended a warm welcome to Dr. Crisp of Denver, U.S.A., who was present at the meeting, and who later took a prominent part in the discussion.

Mr. M. S. MAYOU then opened the discussion on ophthalmia neonatorum. He said that his experience

of the subject had been gained entirely in the London area; and especially in St. Margaret's Hospital, an institution set apart by the London County Council for the treatment of ophthalmia neonatorum. Giving figures of the notifications of ophthalmia neonatorum and the admissions to St. Margaret's Hospital, he mentioned that during the years 1919–21, twelve children were discharged blind in both eyes; whereas during the years 1922–30 there were only three such cases. The number of cases notified in London of recent years had not decreased. He then discussed the histology and histo-pathology of the conjunctiva at birth. With regard to the bacteriology of the condition he found that the gonococcus occurred in 60 to 65 per cent. of the cases, and that, of the remaining organisms, the streptococcus was the most dangerous, frequently leading to perforation and panophthalmitis. He laid stress on the question of the development of local immunity as an important factor in the clearing up of the disease, and thought that it was bound up with the round-cell exudation which took place after the acute stage had subsided. He then dealt with the question of treatment and nursing as carried out at Margaret's Hospital. He strongly recommended open-air wards. By comparative methods he came to the conclusion that the best method of treatment was to wash out the conjunctival sac with eusol (1 in 10), after which the sac was filled with acriflavine (1 in 1,500 of castor oil). Mr. Mayou deprecated the use of silver nitrate as a prophylactic. Attention to general health was of enormous importance, and he emphasized the necessity for breast-feeding if the infant was to do well.

Dr. H. HAWARD BYWATER (Liverpool) emphasized the necessity of institutional treatment for ophthalmia neonatorum. Co-operation with the local health authority was essential. He described the arrangements made between the city health authority and the St. Paul's Eye Hospital at Liverpool, which had existed since 1907, when a special ward, the first of its kind, was commenced by the late Dr. Nimmo Walker, into which the mother was admitted along with the child. He gave an outline of Dr. Nimmo Walker's original scheme (*British Medical Journal*, April 5th, 1907) and stated that the Local Government Act, 1929, had made it easier to give institutional treatment. He showed slides demonstrating the hospital treatment at St. Paul's Eye Hospital. Further progress would be made if there were greater co-operation between the ophthalmologist and the obstetrician.

Dr. CRISP agreed with a suggestion made by Mr. Maddox as to the application of heat in the treatment of the condition, and suggested that Shahan's thermophore might be employed. The discussion was continued by Dr. WHITESIDE ROBERTSON and Colonel R. E. WRIGHT, I.M.S.

In reply, Mr. MAYOU said that heat could not be applied strongly enough to kill the gonococcus, but that cold could be so applied, which also prevented swelling of the lids. He discussed the question of prophylaxis and the dangers of tattooing.

SCHOOL MYOPIA

Mr. ARNOLD SORSBY then read a paper on school myopia. He discussed the recent work of Steiger, which emphasized the unity of the different spherical refractive conditions, and showed that some myopes at least must be regarded as normal variations. He stressed the necessity for taking into account the refractive power of the cornea and lens, since there were very great variations in the axial length. He thought it unlikely that the problem of myopia would be solved without intensive study in its breeding-ground—the schools. Contributions to the discussion were made by Dr. INGLIS POLLOCK, Mr. GIRI, Mr. BISHOP HARMAN, Dr. MARION GILCHRIST, Dr. PRIMROSE, Dr. SHURR, and Dr. CRISP. Mr. MADDOX suggested giving calcium and pilocarpine in advancing school myopia.

Mr. BISHOP HARMAN read a vigorous and practical paper on the eyesight of motor drivers, and recommended that the eye tests for drivers should be less narrow, and that the field of vision, the colour vision, binocular vision, and adaptation should also be taken into account. Mr. ELMORE BREWERTON read a paper on sclerectomy, its difficulties and dangers. He gave an account of his usual practice, and discussed the various complications which had come to his notice.

SECTION OF ANAESTHETICS

Wednesday, July 22nd

PROGRESS OF ANAESTHESIA

In his introductory remarks the President, Dr. H. P. FAIRLIE (Glasgow), who was in the chair, referred to the recent death of Dr. Dudley Buxton.

Dr. R. J. CLAUSEN opened a discussion on the progress of anaesthesia. Reviewing the conditions under which anaesthesia was now practised, he said that it was impossible to assess accurately the state or progress of anaesthesia throughout the land, on account of the large number of small institutions in which operative surgery was performed. He considered that insufficient individual attention was paid to the patient, and that the rapidity of operations in hospitals militated against efficient anaesthesia. In his opinion, mask and drop-bottle methods with chloroform and ether were too prevalent, while the value of rebreathing and the dangers of prolonged open etherization were not fully appreciated. Local, regional, and spinal methods of anaesthesia had not been sufficiently exploited, and gas anaesthesia—particularly ethylene anaesthesia—was not adequately utilized. Dr. Clausen emphasized the necessity of adequate premedication. No patient should come to operation without morphine or one of the basal anaesthetics. He mentioned the value both of CO_2 for post-operative ventilation of the lungs, and of the intravenous adminstration of glucose for vomiting. The absence of team work in investigating anaesthetic methods was regrettable, and he suggested that, in teaching hospitals, an attempt should be made to classify and investigate records. The main shortcomings of anaesthesia were twofold, and could be ascribed, first, to tradition and routine, and secondly, to economic considerations which hampered the employment of many special forms of apparatus.

Dr. K. B. PINSON (Manchester) considered that, in spite of the phenomenal success of synthetic chemistry, the future of general anaesthesia did not lie in the advance of chemical science. He was impressed by the outstanding and cardinal virtues of nitrous oxide, but thought that ethylene was a superior anaesthetic, particularly for dental work. This gas had a powerful odour, but this was not appreciated by the patient, he had used it extensively in dental work, and confidently recommended its employment for this purpose. For general surgery circumstances were so different that he felt that nitrous oxide was as good. Dr. Pinson agreed that apparatus for the administration of gas was imperfect. A good apparatus should have large dials indicating the contents of the cylinders, the flow rate, and the proportion of gases in the mixture. Above all, there should be no leaking. Such forms of apparatus were not portable, and he felt strongly that this, together with economic considerations, pointed urgently to the abolition of nursing homes and the reception in hospitals of all classes of patient. Dr. H. W. FEATHERSTONE (Birmingham) said that progress in anaesthesia had been made not merely in the elaboration of

technique but in the judgement of the administrator. The anaesthetist should secure the safety of the patient from the anaesthetic point of view, and insist upon comfort for the patient both before and after operation. Open ether had many advantages. The numerous layers of gauze employed provided a method of securing wide control. Thus with a correct thickness of pad and careful addition of ether, the mask would contain in its cavity a supply of ether gas, instead of the irritating fog of ether particles which might be caused by careless drenching of the mask.

Dr. Ross Mackenzie (Aberdeen) stressed the importance of co-operation between the surgeon and the anaesthetist. The fact that the latter frequently met the patient for the first time in the anaesthetic room did not lend itself to the best results. He considered that the pre-operative use of atropine protected the patient against cardiac inhibition. He had compared the notes of 1,000 chloroform anaesthesias without atropine with those of 1,000 similar anaesthesias with atropine. The latter group rarely gave the slightest anxiety, while the former frequently showed signs of cardiac inhibition. Dr. Bessie Cook (Doncaster) gave an account of 1,109 cases which had been given gas and oxygen, 1,777 chloroform and ether, and 250 local anaesthetics. In the first 500 of the first two series there were 20 deaths following gas and 30 after ether ; 43 per cent. were not sick after ether, and 56 per cent. were not sick after gas, while with the latter group the average stay in hospital was two days less. Dr. C. Langton Hewer considered that operation lists should be curtailed ; after eight or nine major operations neither the surgeon, anaesthetist, nor nurses could give the same degree of skill to the last case as to the first. Most anaesthetic rooms could be improved ; they should be quiet, and the appearance should be as far removed as possible from that of the operating theatre. Co-operation between the surgeon and the anaesthetist was essential for the best results. Dr. Hewer mentioned four notable advances: (1) the great increase in the employment of gas anaesthetics ; (2) the introduction of basal narcotics ; (3) the adoption of " de-etherization " with carbon dioxide ; and (4) the introduction of percaine to local and spinal analgesia.

Dr. A. H. Macklin (Dundee) was glad to find that N_2O with O_2 and CO_2 was returning to favour. In an unselected series of over 500 cases he had secured complete muscular relaxation, even in high abdominal operations, while the post-operative advantages were overwhelming. To secure complete relaxation it was essential to add an asphyxial element ; but with nitrous oxide and oxygen the asphyxiation was under control and differed considerably from the " tissue asphyxia " resulting from all forms of deep surgical anaesthesia. It was necessary, however, to have an apparatus capable of instantly cutting off the anaesthetic supply, and, if necessary, of inflating the lungs with oxygen and carbon dioxide. Dr. Strange (Wolverhampton) said that morphine should not be administered indiscriminately as a pre-operative medicament. He gave 1/50 grain of atropine as routine. Dr. Adams (East London, South Africa) asked for information regarding the most useful forms of gas apparatus.

Spinal Analgesia

Dr. W. Howard Jones opened a discussion on this subject with a paper entitled " Subarachnoid block, general analgesia, ' spinal ' anaesthesia, respiratory paralysis, fallacies and methods." He first mentioned several fallacies regarding this subject, and stated that Barker had been the first to demonstrate the important fact that a drug could not spread upwards in the intrathecal space by a process of simple diffusion. Surveying the present position of spinocain and durocaine, he said that the rate of absorption of the volatile alcohol was more rapid than the non-volatile novocain, and, as a consequence, the dosage of the latter was so high that the amount absorbed into the blood caused a general analgesic state. He then described the method of gravitational diffusion, which was inaccurate, wasteful of power, and uneven in distribution. He quoted Koster's experiment of applying novocain solution directly to the medulla and upper cervical cord of animals, and remarked that the results obtained depended on the direct action of the drug, through the pia mater, upon the conduction tracts. He thought that the danger in intrathecal administration resulted from absorption of the anaesthetic into the blood stream, with subsequent paralysis of the vasomotor and perhaps of the respiratory centre.

Dr. H. K. Ashworth (Manchester) said that with stovaine the drug was fixed by the nerve roots, as it could not be moved ten minutes after injection. Gravitational diffusion proved an accurate method of control with this drug. He criticized all hypobaric solutions, because sooner or later they became isobaric, and finally hyperbaric, but he agreed with Dr. Jones that spinal analgesia was unsuitable for operations above the diaphragm. Dr. Ashworth urged the use of this type of anaesthesia in cases of acute intestinal obstruction. He considered that, theoretically, the combination of spinal anaesthesia with basal hypnotics in non-urgent surgery was ideal, but the greatest drawback to the method in question was our lack of knowledge concerning it.

Mr. T. P. Dunhill described some illustrative cases in gastric surgery which had been operated upon under spinal analgesia. This method was advantageous because there was great muscular relaxation ; post-operative effects were reduced to a minimum, and the patient could breathe deeply and adequately. Mr. Basil Hughes (Bradford) said that the ideal spinal analgesic should contain a drug which could act efficiently in the highest degree of dilution. With a strongly hyperbaric solution absorption of the drug into the blood stream was a very real menace. He had had no anxiety with spinocain, but he could not say that about stovaine. Since the use of a fine lumbar puncture needle the incidence of headache had practically disappeared, and since the universal adoption of spinal analgesia for major abdominal work, his mortality had been reduced by 50 per cent.

Mr. A. Dickson Wright did not regard percaine as superior to novocain. He agreed with Dr. Howard Jones that rapid absorption of novocain into the blood stream caused a fall in blood pressure. Other factors which must be considered in this connexion were paralysis of the sympathetic fibres in the thoracic anterior nerve roots, the severity of the operation, fear, and haemorrhage, which produced a greater fall in blood pressure with spinal than with other forms of analgesia. Mr. Wright regarded Horner's syndrome of small pupils and sunken eyes as a sign of a very satisfactory injection. The tranquil respiration facilitated upper abdominal operations, while this form of analgesia was ideal for intestinal obstruction, fractures of the lower limbs, rectal, bladder, and prostate operations.

Mr. A. Wilfrid Adams (Bristol) said that spinocain was an efficient drug ; but the possibility of a harmful novocainaemia was important, and so he did not, as a rule, give more than 2 c.cm. of spinocain. He regarded this drug as specially suitable for upward controllability. Routine operations were readily performed by the busy surgeon with ether and chloroform, and more than minor virtues were necessary to move him from a well-tried method.

The President stated that he had used percaine, and considered it an ideal drug for cases of intestinal obstruc-

tion. He had not observed post-operative headache since employing this drug, but on one occasion it had failed to produce analgesia. Dr. LANGTON HEWER said that the method of direct injection of dilute percaine in hypotonic saline was, in his opinion, a great advance upon previous techniques for high abdominal surgery. He considered that an injection between the first and second lumbar vertebrae was not uniformly safe, and, accordingly, he advocated a lower puncture. He deprecated the use of spinal anaesthesia for operations above the diaphragm. In reply, Dr. HOWARD JONES stated that he did not like to withdraw large quantities of cerebro-spinal fluid. Answering the President's question, he said that failure with percaine might be due to precipitation, and in this connexion he advocated the employment of buffered solutions.

SECTION OF DERMATOLOGY

Wednesday, July 22nd

PRURITUS ANI

The first meeting of the Section, with Dr. HENRY MACCORMAC (President) in the chair, was devoted to a discussion on pruritus ani, opened by Colonel MACARTHUR, who confined himself to discussing that variety of the disease caused by the threadworm *Enterobius vermicularis*, a variety which, he said, was much more common than was generally suspected. The ingested ova hatched in the duodenum; they lived for the most part in the caecum and appendix, but the gravid females descended to the rectum for the purpose of laying their eggs, which they did just inside the anal canal. It was their wriggling movements which caused the pruritus. Auto-infection was the rule, the ova being conveyed by the fingers contaminated by scratching. In addition to the pruritus—always most intense at night, but ceasing some time before morning, and only occasionally experienced in slighter degree during the day—various reflex phenomena might develop—for example, indigestion and frequency of micturition. These might mask the true diagnosis. Owing to lacerations and abrasions of the anal region, perianal eczema might be set up, but, on the other hand, there might be very little local injury in cases of many years' duration. Nasal itching was very common—possibly a provision of nature for ensuring that the infected hands were brought into the neighbourhood of the mouth. The accurate diagnosis of enterobiasis depended on a rectal washout administered when the pruritus was active. Three or four ounces of saline were all that were necessary to wash out a rectum previously emptied of faeces, and this fluid, returned into a suitable receptacle, must be carefully examined for threadworms. Care must be taken that shreds of mucus, etc., were not mistaken for the worms. Treatment was divided into three parts. The first was prevention of auto-infection. For this reason the hands must be thoroughly washed every time that the surface of the body or an undergarment was touched. Any laxness in this respect would be followed by vexatious re-infections. The second consisted of removal by lavage of the adult female worms which had migrated to the rectum. For this purpose the best thing was a strong solution of salt and water (two tablespoonfuls to the pint). Four ounces was a sufficient quantity, and when it was ejected, after probably not more than a minute or two, the itching would have ceased completely. It was essential that the patient should carry out this treatment himself, as it was useless when the pruritus was not felt. Thirdly, antihelminthic drugs should be given in the hope of destroying the parasites before they migrated to the rectum. These were far less efficacious than the rectal washouts, and patients who had found that the rectal injection gave instant relief preferred as a rule not to be inconvenienced by purgative drugs, even although the course of treatment might be shortened thereby. Finally, the speaker said that he did not know what proportion of cases of pruritus ani were due to enterobiasis, and he submitted that this should be considered as a possible cause in every case of pruritus ani met with in adults.

Mr. W. P. GABRIEL said that pruritus ani was commonly seen at St. Mark's Hospital. He laid great stress on the systematic questioning and examination of patients. He enumerated seven causes of the complaint: (1) lack of cleanliness; (2) excessive local sweating; (3) leak of mucus owing to prolapse and proctitis; (4) as an occasional symptom of high carcinoma of the rectum; (5) leak of liquid paraffin when taken in excess; (6) pruritus due to threadworms, which he had discovered by repeated proctoscopy; (7) a few remaining cases devoid of any obvious cause, in which the pruritus symptom might be elevated into a disease. He spoke highly of A.B.A.—a 3 per cent. solution of aniseed oil—as a form of treatment, which he employed by injecting it round the rectum with a view to interrupting the anal nerves. He had treated sixty-six cases in this way, with good results in forty-two. Only in three cases had he failed entirely.

Dr. HERBERT BROWN (Glasgow) had circularized all the patients he had treated for this complaint during the last ten years, and had been much chastened by the answers received. There had been a large percentage of relapses. Of the dermatological conditions which might cause pruritus he thought the most important was lichen simplex chronicus. No less than 18 per cent. of all his cases showed lesions of lichen simplex chronicus in other situations. He stressed the importance of team work in elucidating the origin of obscure cases. In treatment he had found A.B.A. useful when the irritation was limited to one spot. *X* rays, though undeniably useful, must be given with the greatest precautions.

Dr. DOWLING said there were seven causes of pruritus, of which he considered mycelial infection the commonest. He had had good results from A.B.A. Dr. HALLAM (Sheffield) said that many cases were due to a tag of anal skin. He uttered a warning against the indiscriminate use of *x* rays. Dr. AGNES SAVILLE had treated no fewer than 200 cases, but was still learning. Only lately had she grasped the importance of liquid paraffin as a cause. She emphasized the point that the anal region should be protected from faecal irritation by the use of vaseline before defaecation. Dr. BEATTY (Cardiff) described itching as subliminal pain. Mr. DICKSON WRIGHT had not had much success with A.B.A., but he had in twelve cases divided the nerves feeding the pudendal area through an incision midway between the anus and the ischial tuberosity, with good results. No incontinence had followed. Dr. ANDERSON (Ruthin Castle) said that very few patients went to Ruthin Castle to be treated for pruritus ani. Dr. ROXBURGH advocated the use of alcohol injections round the anus. He found *x* rays useful in clearing up the dermatitis, and in idiopathic cases. Dr. J. D. ROLLESTON mentioned that tabes might be a cause of anal pruritus. Dr. HALL (Brighton) spoke of the frequency of enteroptosis and stasis.

All the speakers without exception expressed their appreciation of Colonel MacArthur's work on enterobiasis, and their resolution to keep prominently before them the possibility of threadworms as a cause of anal pruritus in future. Subsequently the following short papers were read: "Onychia as an occupational disease," by Dr. HALDIN-DAVIS. "The etiology of dyshidrosis," by Dr. G. B. DOWLING. "The treatment of lichen planus by *x* rays to the spine," by Dr. McCaw (Belfast).

SECTION OF ORTHOPAEDICS

Wednesday, July 22nd

COMMON INJURIES OF THE KNEE-JOINT

At the first meeting of the Section of Orthopaedics Mr. A. S. BLUNDELL BANKART was in the chair.

Mr. NAUGHTON DUNN (Birmingham), in opening the discussion on the differential diagnosis and treatment of the common injuries of the knee-joint, said that, with increasing experience of injuries of the knee-joint, he became more and more convinced that accurate diagnosis of the exact nature of the injury was in many cases quite impossible. Referring briefly to the normal anatomy of the knee-joint, he pointed out that, as it connected the two longest bones in the body, the leverage on it is enormous, while to meet this disadvantage Nature had provided it with powerful muscles and strong ligaments, which latter limited all movements except flexion. Rotation was only possible in flexion, and in his experience it was strain of the flexed knee which provided the great majority of injuries to the intra-articular cartilages. Mentioning the twelve bursae which anatomists had described in connexion with the joint, he said that, though surgeons only took note of four as the source of symptoms, possibly affections of some of the less accessible might be responsible for obscure conditions in it. He then reminded the audience that the articular cartilage was avascular, and so had little power of repair; while the synovia, which oiled the joint, was richly supplied with sensory nerves, and thereby a great source of pain. Inflammation of the infrapatellar pad of fat, which was extra-synovial, might simulate swelling of the joint itself. A table was then shown of the diagnoses of 522 consecutive cases of injury to the knee-joint, of which 179 were considered lesions of the internal semilunar cartilage (139 being confirmed by operation), and 71 of the external cartilage (46 confirmed by operation). Lesions of the internal lateral ligament accounted for 34, and loose bodies for another 34—all the other groups being represented by quite small numbers. Many indefinite cases responded to manipulative treatment, suggesting that they were due to adhesions; probably another large group were cases of subacute infective arthritis. The speaker considered that one might safely diagnose a lesion of an intra-articular cartilage, provided there was a history of recurrent locking, with pain and tenderness limited to the attachments of a cartilage, while the knee became normal in function between the acute attacks, and *x* rays were negative. The types of injury found at operation were: tear of the anterior part, and tear of the posterior part, or bucket-handle tear. Several cases were quoted in which the cartilage appeared normal, and yet the symptoms disappeared after its removal. In one or two with internal tenderness and pain it was found that the external cartilage was the one actually damaged. However, when the history had been typical of cartilage trouble and the internal one was found normal, Mr. Dunn advised exploration of the outer side of the joint. He referred to the difficulty presented by a slipping patella, as the patient was seldom seen by the medical attendant during the actual dislocation, while the history might suggest an internal cartilage. He pointed out that the locking caused by loose bodies was seldom a fixed one. Lesions of the internal lateral ligament were caused by trauma to an extended knee, just the reverse of cartilage injuries, and tears were seldom complete, so that many recovered completely without operation. Where damage to both ligament and cartilage was suspected, it was best to wait for healing of the ligament before operating to remove the cartilage. For fractures of the [illegible] joint he advised gradual extension of the joint by fact that [illegible] before operation was resorted to. A specithecal spacin[illegible] the present [illegible] a loose body detached from the back of the femur, which had a bursa round it, and had given rise to very persistent symptoms. In connexion with injuries of the extensor apparatus, Mr. Dunn suggested that the greater the flexion of the knee at the time of injury the higher the level of the lesion. He showed an *x*-ray of a bipartite patella, which might easily be mistaken for a fracture. For crucial ligament injuries he recommended conservative treatment as far as possible; operation, in his experience, had not been able to restore the normal function of the joint. In regard to operation for internal cartilages he advised a small incision, nearly vertical, so as to avoid a branch of the internal saphenous nerve, which had caused a painful neuroma in seven cases after operation.

In the subsequent discussion all speakers congratulated Mr. Naughton Dunn on the thorough manner in which he had covered the field, and on the large material and accurate records on which his paper was based.

Sir ROBERT JONES (Liverpool) agreed with Mr. Dunn that, in many derangements of the knee, diagnosis of the exact lesion was impossible, and that cases with the classical symptoms of cartilage injury might prove to have something quite different. He thought it was usually possible to differentiate between damage to an internal and external cartilage, though "locking" was common to both; but the pain was usually referred to the correct side in the first attack, whereas in recurrent cases it might be felt on the other side, so that a careful history was valuable. It was the unlocking from flexion, sudden and complete, which was of chief diagnostic value; if the flexion only yielded gradually, it was probably not a case of cartilage injury. Clicking was most common with external cartilages, while pain on abduction and adduction suggested a ligament injury. He was surprised at the high percentage of external cartilage cases in Mr. Dunn's figures, as were most of the subsequent speakers, the usual proportion being quoted as from 1 in 7 to 1 in 30, in contrast to Mr. Dunn's 1 in 2½. The speaker pointed out that many cases of cartilage injury had only one attack; therefore he advised reduction by manipulation for the first, care being taken that the reduction was really complete, which it was not until free extension and entire relief of pain had been obtained. He treated cases by two to three weeks' rest in complete extension after reduction. Operation was desirable in every recurrent case, and imperative, if effusion kept occurring, in an athlete. Even if the cartilage appeared normal when the joint was open it should be removed completely.

Mr. H. A. T. FAIRBANK pointed out that in cases where there was no muscle-spasm the extreme wasting of the quadriceps could not be due to fatigue, but must be of the nature of a reflex inhibition. He suggested that sometimes obscure pain might be due to lesions of the popliteus tendon, the ilio-tibial band, or the insertion of the semimembranosus. He advised the use of a blunt hook to bring the posterior end of a cartilage into view at operation, and he recommended that all true ligament tears (not mere strains) should be sutured. He thought that lesions of the articular cartilage were not uncommon, and that fractures of the tibial spine were of two types—a shearing by the internal condyle, giving only slight displacement and not needing operation, and a tear of an anterior strip by hyperextension, which demanded suture or pegging. Dr. W. ATTLEE (Eton) gave a very interesting account of the lesions in schoolboys, the most common being an effusion associated with rapid atrophy of the thigh muscles. This soon cleared up if a few days' rest in bed were followed by regular exercise on a bicycle and rowing. Pain referred to the tibial tubercle was very common in the football season, but cleared up when this was succeeded by the running season, painful heels taking its place. Various *x*-rays were demonstrated,

some showing abnormalities in knees which had no symptoms. Mr. ROWLEY BRISTOW agreed with most of the points made by Mr. Dunn, and emphasized the importance of early exercise after operation for removal of cartilages; he encouraged lifting of the limb off the bed a few days after operation, gave faradism from the sixth day, and got the patient up on the tenth day. Mr. MCMURRAY (Liverpool) said the term "locking" was misleading, and should be abandoned. He again drew attention to his method of diagnosis by flexing the knee completely and then rotating it at each angle as it was extended, which enabled the site of injury to be localized by the pain and click.

Mr. OLLERENSHAW (Manchester) showed lantern slides of some interesting *x*-rays, and Mr. R. C. ELMSLIE, Mr. STUART (Birmingham), Mr. LAMING EVANS, Mr. ROCYN-JONES, and Mr. AITKEN joined in the discussion, to which Mr. DUNN replied.

SECTION OF MEDICAL SOCIOLOGY

Friday, July 24th

THE NEED OF EDUCATION IN QUESTIONS OF SEX

The PRESIDENT (Dr. L. A. Parry) before calling on the speakers, referred to the death of Mr. E. B. Turner, who was to have been a Vice-President of the Section, and whose work in all branches of medical sociology was so highly valued.

The opening paper, by the Rev. T. WENTWORTH PYM, is printed in full on page 186 of the present issue of the *Journal*.

In starting the discussion, Mrs. NEVILLE ROLFE (British Social Hygiene Council) referred to the magnitude of the problem. There were some five and a half million children under 14 in the elementary schools, and between three and four million young people between the ages of 14 and 20, the majority of them already in occupations. During the last fifteen years the scientific outlook on life had been more and more assimilated. Young people could now be appealed to on the ground of scientific knowledge and the application of science to life, but up to now it had appeared as if only those truths in science had been taken and used which would minister to material welfare, and the immense advances made by science in the understanding of human nature had been ignored in organized education. Young people of to-day would only accept teaching of the scientific accuracy of which they were assured, but they did respond to the appeal to their responsibility. What was required in this subject was not a hurried instruction of the physiology of sex unrelated to life, but of life itself. It was the medical profession, particularly the individual private practitioners, who were largely responsible for creating the social values pertaining to conduct in its relation to health, which values in turn influenced our social customs. It was useless for the educationist to talk about moral values if the medical man or woman did not support the line of teaching which the educationist gave. At the present moment, scientific knowledge as to what was normal in sex life was very deficient. The best that could be done was to focus the attention on the need for research. One must be prepared to say "I do not know" when one did not know, and not give hasty answers, based on moral values, to what were really scientific questions; that was not going to be of any help to the teacher. Her council had tried to devise a means of approach to the adolescent, and was now studying the problem of preparation for marriage and the hygiene of marriage. She hoped that the result would be a handbook giving in succinct form the results of physiology, psychology, and anthropology, in so far as they bore on this problem.

The BISHOP OF CHICHESTER confined his remarks to two aspects of the question: the nature of the teaching, and the person who should give it. In one's own case the initiation into these facts took a very considerable time, and even though the instruction given might be more systematic than it was in the youth of those present, the fact that it took a long time was not at all a bad thing. As Canon Pym had said, there were certain questions which a child asked in extreme youth, and other questions which he asked as he grew a little older. Each question should be answered frankly and simply as it came. By the time the child was 8 or 9 it was possible for a considerable amount of knowledge to have been gradually and simply received, thereby forming a basis for the knowledge acquired at a later period. The Bishop felt that the imparting of sex knowledge ought to be on a background of something much wider than sex, and sex ought not to be a special segregated subject. Thoughtful teachers would see the child's response coming during lessons in biology, elementary science, and in physical instruction. He thought that religious teaching also had a very important part to play, and it was well to rely on the Church impressing upon its children that the body was a trust given by God. As to the persons who should give sex instruction, ideally it should be the parents—well-informed and high-minded fathers and mothers, full of discretion. But often that was impossible, and in any case the parents could not do it alone. There must be collaboration, and the teachers, clergy, and doctors should be ready to take their part. The doctors, after seeing a family through illness or through a succession of births, should be ready to help the parents and children to see what was good for them at any given stage. The extraordinary complexity of the problem had to be recognized, including the fact that the information desirable to be given differed widely according to the homes from which the children came. If there was to be a single authority for giving direct instruction in the proper way at the proper time—and that was a large assumption—he thought it must be the school. The matter was not so difficult in public schools for boys. In the elementary schools the problem was much more acute. But if the school was not going to try and devise means, with the help of the medical officer and the parents, to give the instruction at a particular time when the moment had come, he did not know from what source the instruction was to come.

Major STEPHEN FOOT (House Master at Eastbourne College) spoke in the first place of the need for sex education. As a result of his experience as house master he was convinced that the need was vital. Some persons maintained that it was a mistake to tackle the subject at all. They considered that it put ideas into a boy's head and awakened a curiosity he would not otherwise possess. The speaker believed that to be "unadulterated rot." In nine cases out of ten, where a boy went seriously wrong in his sex life, it was due to not having received proper instruction in the functions of the body. An immense amount could and should be done in early years by parents and preparatory school masters, but he did not believe that full instruction in the functions of the body could be provided until the boy reached the age of 14 or 15. He had never yet come across a boy who did not admit that the earlier instruction which he had had failed really to satisfy his curiosity. As to the person for sex education, he started with the idea that the person to give such education was the parent. The first parent he interviewed on the subject, however, was a doctor. He asked him if he had talked to his son, and the father replied bluntly, "No, that's your job," and he went on to give three reasons for saying this. The first reason was that, on account of the personal implications, it was more difficult for a parent to give this instruction to his own child than for anybody else in the

world. Secondly, the task was in any case a difficult one, and one which improved with practice. This particular father said that he thought he would be no good at it until he came to his ninth or tenth son. Finally, this father thought that the matter was best regarded by a boy as part of his education, something that he had to be taught, and therefore it came more naturally from a schoolmaster. He agreed with this doctor that it was a task which the house master should undertake, and if he were a head master he would never appoint a house master unless satisfied that he was prepared to undertake the task and was competent to do so. As to the method of sex education, the speaker had no time then to do more than state his conclusions. It should never be collective. Books were of no use. In the first place, suitable books did not exist; and, as all boys were different, it was necessary to adapt oneself at a moment's notice to a particular case, which could not be done by literature. The method, again, should be thorough and complete, leaving no lurking curiosities, and, finally, it should be regarded as a sacred duty, and one to be approached in the spirit of prayer.

The Rev. James Reid (President, Free Church Council of Eastbourne) held that the proper person to give information was the parent. This was important from the point of view of breaking down the barrier of reserve between parent and child. The maintenance of such reserve in this respect might mean the perpetuation of the barrier into later life. It was also important that the parent should give the information because that would go far to ensure the right feeling and tone. It was not enough to dispel fear. Fear was the guardian of the sacred in undeveloped states, before right values came to bring the proper sanction against abuse. Hence, it was not enough to give the information naturally, as in the case of information about a plant or a machine. The sex function was not neutral to the personality, for body and spirit were intimately related. If these values were to be associated with sex, the information must be imparted by one towards whom affection and respect were given. This meant that the best results depended upon the right kind of home. The speaker concluded by saying that the true object of sex education was not the avoidance of dangers, but guidance into wholesome relationships between men and women, married and unmarried.

Dr. Christine Murrell said that the vast majority of those present would agree that the biological part of sex instruction might be given in classes, though probably it ought to begin ideally with the parent in the home. When it came to other sections of sex instruction, she wished to put in a word for the hygiene of the adolescent period, which should certainly be personal and intimate. On the very difficult question of the instruction of the adolescent as to how to become a full adult and desirable member of human society, to her mind, the question of instruction was really dissolved in the greater importance of the instructor. When it came to a question of advising the young, the vast majority of men and women with good intentions were bewildered. This was not because sex itself was not tremendously honourable, but at the back of the mind was a feeling of shame. This had nothing to do with normal reticence; it was not shame of sex, but was due to the wrong methods and customs of a great many with regard to sex, which created the difficulty. The person who gave instruction, therefore, must be one who had had many years' preparation. Barring certain abnormal cases, ought it not to be the parent himself or herself who chose the instructor? In fact, they could imagine any greater compliment to an older friend than to be asked by a younger for advice on this the present [illegible] young would not ask for such advice unless they "sensed" that the person asked was ready to respond. The young were extremely sensitive to atmosphere; they were reticent, but normally physiologically curious, and they would go to the person who, they felt, would answer the question in a suitable and sympathetic manner. That person might have to impart information, to say what he or she thought desirable, and to instil an ideal, but not to instruct. The ideal, in her view, was self-respect. That was the only safe thing with which a young man or woman could be equipped on going out into the world. It was above all things the character of the older person that was going to help the younger. She had come across cases where the mother was the best adviser for the boy and the father for the girl, but in general she thought it was for the mother to advise the daughter and the father the son. Self-consciousness must as far as possible be banished, and above all things that sugary sentiment, which was really a defence mechanism to hide the fact of shame, must disappear.

Dr. F. E. Fremantle, M.P., pointed out that most of the rising generation had no blind respect for authority and no patience with mystery, with which this whole problem was veiled. If the right of inquiry were conceded to the younger generation, some advance would be made. What was the real force behind the whole of the sex question? It was primarily the necessity for the race to continue. He believed that the true way of approach to this problem was to deal with the question of sex and of marriage as an essential part of the national life, to point out the duty and the necessity of the individual citizen to aim at a pure marriage and a family brought up in the fear of God and the service of the State, and to point out the enormous advantage of a happy—which meant a chaste—married life. The ideal of chastity and chivalry could be made to appeal greatly to boys and girls. He thought that the medical profession had been somewhat to blame for the discredit into which the subject had fallen, because the textbooks of medicine had failed to deal with this matter. He remembered writing to Professor Starling many years ago pointing out that his famous textbook on physiology hardly dealt with sex at all, and Starling's reply was that the subject was too difficult.

Dr. Israel Feldman said that many views had been advanced that morning from which he profoundly disagreed. He distinguished between sex education and sex instruction. As to sex instruction previous speakers had vastly exaggerated the difficulty of imparting knowledge. Such difficulty as there was had been created in an entirely artificial and unnecessary way. He was radically opposed to individual instruction on sex, because that created the artificiality of atmosphere which it was most desirable to avoid. It was all wrong, having given a boy some information, to tell him not to discuss the matter with other boys. It should be an open thing. If he desired to discuss sex, let him do it with the same openness as he would discuss sport. Biology was the royal road of sex instruction, being the explanation of the normal functioning of living things. With regard to sex education, he asked how many medical persons present had ever been taught about the significance of masturbation, or of birth control from the medical point of view, or as to what were the effects of continence. The trouble was that the elders had no philosophy for themselves. That was where the Church had beaten the medical profession, for the Church at any rate had a definite and specified outlook for guidance in sex education, though up to the present it had not been in the position to give sex instruction. The answer of the Church, however, would not satisfy the present generation. The whole matter was in the melting-post, and it would go from bad

to worse if they continued to think that they could tell the young anything which they themselves did not implicitly believe.

Dr. J. L. BASKIN said that Dr. Stoddart, who had interpreted Freud's work, had shown clearly that at 4 years of age children became extraordinarily curious about themselves; later this curiosity was submerged in the unconscious. At 11 years of age it again came to the surface, and the boy or girl took a deeper interest in the matter. Later, at puberty, definite psychological conceptions were formed, and then it was that precise information should be given. It was a great mistake to pick out education on sex matters as apart from education in biology in general. With regard to the method, it was in a general superficial way an excellent idea to give information collectively, but in a class there were always those who wanted a little more than the others. An important thing, hardly touched upon in the discussion, was the question of what was to happen to the young man or woman between 16 and 25. The speaker urged the importance of sport and the preaching of continence. The self-absorption of the elements of procreation would not only imbue the individual who was the recipient thereof with courage and self-reliance and initiative, but would also engender a spirit of tolerance for others who were not gifted in the same way. He desired the formation of a committee of members of the medical profession, clergymen, and teachers, to arrange the requisite advice.

Dr. COURTENAY C. WEEKS (Beckenham) described some lectures in which he had taken part on behalf of the education authorities of Leicester and Derby. A letter was sent to the parents of children who were leaving school stating that lectures on sex hygiene would be given to the scholars, and asking the parents, if they approved, to let the children attend. An increasing number of parents and scholars had availed themselves of these lectures, and it had been a revelation to him to hear what some of the fathers had said following upon the lectures to elementary school children. In many cases a great change had been wrought in the mentality and atmosphere of the school as the boys were admitted into the knowledge of the glorious responsibility and trusteeship of life. Collective instruction of boys and girls on this vital subject was neither impossible nor to be deprecated. The subject should be dealt with normally and concisely, and then left alone. After all, sex was only part of the larger difficulty of the conflict of life. These children called for the exercise of the sympathy of their elders, for at the age of 11 or 12 a child might have the desires and passions of grown men and women without the mental control.

In further discussion Dr. J. K. LOVE (Glasgow) referred to the advantages of a study of Mendelism, which he considered to be the key to all proper sex education for young children. Dr. MOORE remarked that nothing had been said about sublimation—that by some means or other children had to be taught how they were in their own particular case to control their sexual impulses and turn them into a useful channel. Miss BRENDER (Social Purity Worker in the Chichester diocese) asked how boys were instructed in public schools with regard to girls, and whether the highest ideal of womanhood was presented. Dr. JOHN BIRCH (Luton) said that as one who had attended many hundreds of confinements he could bear witness that the first question invariably asked by the parents was: "Is the child sound in body and mind?" In that question lay the whole philosophy of sexual conduct. He deprecated the common view that sexual needs had to find sexual satisfaction; he had lived in mining camps, and had been astonished to find the continence of rough men. The proper way was sublimation. Dr. HARMAN TAYLOR (Liverpool) said that his own education in this matter was imparted by one of the greatest of head masters, Dr. J. L. Paton of Nottingham, who brought to the boy mind the sense of mystery, and explained the subject through the avenues of biological science. The ideal solution of the whole problem was through a schoolmaster who had a personality able to influence boys.

Canon PYM, in a brief reply, said that what he wanted to see were some books giving a full list of the sort of questions that young children asked, and the sort of way in which they should be answered.

INTERNATIONAL CONGRESS OF MILITARY MEDICINE AND PHARMACY

More than thirty nations took part in the sixth international conference of military medicine and pharmacy, which was held recently at the Hague. The first main topic of discussion was the recruiting and training of the medical personnel, and the relative advantages of approaching medical students and qualified medical practitioners were debated. It was felt that the opportunities offered by the career of military medicine should be advertised more widely, in order that students might be attracted before they had made up their minds to embark on civil practice. Special post-graduate training ought to be more freely available, and there should be more extensive scope for interchange of medical officers between the various nations.

WAR PSYCHO-NEUROSES

In reviewing war psycho-neuroses the conference took note of the fact that these conditions were not created by war conditions, but that confusional states with an emotional basis were present in a latent form before the final stimulus brought them into the open. The subsequent symptomatology, while comparable with that of similar states in civil life, was coloured by the episodes and conditions of active service, and was consequently of a more serious type, both as regards the patients and their relationship to their environment of duties and responsibilities. Moreover, there was the problem of State pensioning in cases where treatment proved ineffective. The existence of border-line cases, presenting a disorder of conduct rather than a definite neurosis, called for the creation of an expert diagnostic organization, and psychiatrists would have to investigate these patients before any question of punishment could be considered. A neuro-psychiatric branch of military medicine should be established in times of peace on the basis of a central army hospital, accommodating patients primarily for the purpose of diagnosis. Cases seriously ill would be sent elsewhere, and only those capable of being cured within a relatively short time would be retained. In connexion with this, special methods of evacuation from the more advanced parts of the fighting line would have to be planned, in co-ordination with the usual arrangements for the sick and injured. Regional neuro-psychiatric centres should be established throughout each country. Here the primary diagnoses would be reviewed and corrected, definite categories being provided for three classes of patients—namely, the gravely ill requiring institutional segregation elsewhere, the transient and easily curable types which could be dealt with on the spot, and the difficult but still curable cases for which special institutions would be necessary. It was agreed that the organization of such a neuro-psychiatric military service would be much more difficult in countries where conscription was not in force.

HAEMORRHAGE ON THE FIELD OF BATTLE

The two final questions discussed were the best means of dealing with urgent cases of haemorrhage on the battlefield, and the treatment of the sequels of wounds of the

jaws and teeth. In respect of the first it was felt that there should be standardized first-aid equipment for the individual as well as for stretcher units, that further investigations should be made of the later complications of ischaemia following tight bandaging, especially when venous rather than arterial haemorrhage was concerned, and that better arrangements were desirable for instructing those dealing with casualties in the firing line. Consideration was also given to the supply of sterile drugs in ampoules for emergency injections.

Emphasis was laid on the importance of ensuring that the early treatment of wounds of the jaws and teeth was devised on right lines, a dental expert acting in association with the surgeon. During peace specialists should be trained to deal with the various contingencies that might arise, and so bring about the diminution of such unfortunate sequels as infected bony fragments, ankyloses, pseudo-arthroses, and subsequent dental degeneration.

POST-GRADUATE MEDICAL WORK IN GERMANY

The following account of present-day courses for medical graduates in Germany is abstracted from an article furnished to us by Professor Curt Adam, general secretary and organizer of the German National Committee for Post-Graduate Work.

There is no diversity of opinion concerning the necessity for medical post-graduate work in Germany to-day. The university turns out its medical students with an education suited to the prevailing demands of science, but science never stands still, and the doctor must follow if he wishes to keep abreast of the times. For this purpose he must attend special courses, since complex methods of treatment are not learned from a journal or from verbal description at a medical gathering or congress.

ARRANGEMENT OF POST-GRADUATE STUDIES

Now the higher education of doctors is not only a matter of individual professional interest, but concerns the health of the nation as a whole. Of what use to humanity are new discoveries in the realm of medicine if they are not put within reach of the great body of general practitioners? If post-graduate work is to be productive in this sense, it is absolutely necessary that as many doctors as possible should participate in organized courses, so that the general standard of practice may be raised. This means that courses must be so arranged that doctors can attend them without undue sacrifice of time and money. Since compulsory methods of ensuring attendance are impracticable certain conditions are necessary: (*a*) the courses must be free, (*b*) they must be given at least in the immediate neighbourhood of the doctor's practice, and (*c*) they must be so arranged that he can attend them without disturbing his everyday work.

Location

In Germany the organization of convenient meeting-places required a far-reaching decentralization. The number of available universities was not adequate for the purpose, and steps had to be taken to ensure opportunities for post-graduate studies wherever there was a great deal of medical activity. Where large hospitals existed the matter was comparatively easy; it was more difficult in small towns and in the country. In the latter the system of travelling teachers was adopted.

Hours for Study

The most convenient periods for study were found to be from 12 o'clock to 2 o'clock, and after 7 o'clock in the evening. Sunday morning was also popular.

Free Courses

The question of free instruction is an important one in medical post-graduate work as it is understood in Germany. Naturally there are people who regard what is paid for as more valuable than that which is given free. While this may be a true and representative opinion of a large part of the medical world, the payment of fees is not the way to increase the popularity of post-graduate work, or to attract the largest number of doctors. In ideal circumstances the teachers would be sufficiently compensated and the students would have free instruction, even being given a certain amount for taking part in the course. But the necessary expenditure on the part of the State and medical organizations would be almost prohibitive. Happily there are still teachers in Germany who are pleased to give their services for this work without stressing the question of remuneration. Were it not for this widespread spirit of self-sacrificing co-operation, post-graduate education in Germany would not be possible.

Organization

The above-mentioned points, which were not sufficiently emphasized when the possibility of post-graduate work was first being considered, led to the creation of a central committee for medical post-graduate work in Prussia in 1901. The foundation of this committee was followed by the establishment of similar committees in the other German States which met in 1908 as a German committee for medical post-graduate work. These committees are unions whose members consist of representatives of the participating State and municipal boards of the universities, of the hospitals, of the medical profession, and of social medical societies, the direction of the work being in the hands of an official or semi-official doctor. The committees receive funds through their respective Governments, which have realized that it is in the interests of the health of the entire population to have a well-educated medical force. Funds, however, are small, because, as mentioned above, the teachers receive no remuneration. The State committees only outline the general rules and provide for the assembly of as many local committees as possible, these local committees being responsible for the actual work. Up to the present committees have been established in eighty German towns. The medical faculties naturally take over these tasks in the university towns; in others the work is concentrated at the large hospitals. In contrast to other countries, Germany has a very large number of promising lecturers, qualified in every respect to act as college professors.

Post-Graduate Work in Small Towns and in the Country

As the local committees described above are generally located in the large towns, travelling lecturers are sent out from the centres of learning, singly or in groups, with material brought with them or distributed locally, to give lectures to the medical societies of the small towns and villages. In addition, half-hour talks on subjects of post-graduate interest are given at wireless stations by the most prominent authorities on Friday evenings. In this way the country doctor supplements his education. Very often the lecture is followed by long and animated discussions.

Post-graduate work is also promoted by the publication entitled *Zeitschrift für Ärztliche Fortbildung*, sponsored by the State committee and published by Gustav Fischer, Jena. In contrast to the more scientific periodicals it is devoted solely to higher medical education, concerning itself only with such matters as have received scientific recognition and are of use in general practice.

The medical post-graduate education of the country doctor has recently been the subject of reform. Unlike his professional colleague in the town, the country doctor must invariably make a long journey to the locality where the courses are held, and arrange for accommodation. During this period he must also give up his practice or find a deputy. These arrangements involve the expenditure of a considerable amount of money. With the object, therefore, of facilitating his attendance without loss of time and money, the chief medical societies, the Reichs insurance bodies, and the medical post-graduate organizations, have combined to supply the necessary funds. Thus the country doctor may be provided with board and lodging, free of charge, at an institution set aside for post-graduate study. The medical post-graduate organizations cover the fee of the lecturer, and the medical

societies pay to each doctor attending the courses the sum of 125 marks to enable him to compensate his deputy. Courses are held in tuberculosis, venereal diseases, children's ailments, and accident disabilities. According to another scheme, the country doctor may be accommodated in hospital or clinic for a short period, say, from two to four weeks, the medical societies reserving the beds for this purpose. He takes full part in the work of the hospital, and boards along with the other doctors. In this way he is afforded the opportunity of participating in the practical treatment of the patients. Of especial importance to the country doctor is the fact that similar arrangements have been made with maternity clinics.

Post-Graduate Courses for Foreigners

The opportunities for post-graduate work mentioned above are intended primarily for the German doctor, but numerous arrangements have been made to provide facilities for the large number of foreign doctors who come to Germany to study. In Berlin an assembly of docents and professors has been formed to arrange for the provision of post-graduate courses in the holidays. These fall into various classes.

1. Post-graduate courses of short duration (two to four weeks) These are partly general courses in some important field such as internal diseases, diseases of the eye, urology, or cardiology, or practical educational courses in some special field—the technique of examining the heart, dermatological treatment methods, and so on. The courses are held generally in March and October, but they have also been arranged in other months.

2. Post-graduate courses of longer duration. Provision for these is made in the large town hospitals, where, after a general preparatory course, the students do practical work in the sick room, laboratory, and on the dissecting table.

Information Bureau

Of particular interest to the foreign doctor is the bureau in the Kaiserin Friedrich-Haus fur das ärztliche Fortbildungswesen (Berlin, N.W.6, Luisenplatz 2-4), which deals with all questions relating to post-graduate work, facilitates attendance at clinics, and promotes social intercourse. It also gives information about rooms, cost of maintenance, and similar matters. Doctors should get into touch with this bureau before they start on their journey, or as soon as they arrive in Berlin, so that they may derive the greatest possible benefit from their sojourn in the country.

Nova et Vetera

DR. WILLIAM GILBERT

Discoverer of Terrestial Magnetism and Founder of Electrical Science

In the list of Past-Presidents of the Royal College of Physicians of London we find the name of "William Gilbert 1600"; and in the College calendar, opposite the date November 30th, we read: "Dr. William Gilbert died 1603"

Most medical men will not know anything about William Gilbert; others may remember reading, in their early student days, of Dr. Gilbert, physician to Queen Elizabeth, who discovered terrestrial magnetism, and devoted much time to the study of frictional electricity; but few will know anything of his great work. Yet William Gilbert was one of the most distinguished scientific men of his age, and a man to whom physics owes so much. He was born at Colchester, Essex, in 1540. At the age of 20 he took the degree of B.A.Cambridge He had been a student at St. John's College, and later was elected a Fellow of his College. He became M D Cambridge in 1569. For four years he travelled in Italy, and then settled in London in 1573. He became a Fellow of the Royal College of Physicians, then censor, later treasurer, and finally President of the College in 1600.

We are told that Gilbert was a man of means, that he spent money freely (estimated at £5,000) on his books, instruments, magnets, and experiments, and that for twenty years he experimented and speculated on magnetism and frictional electricity. His great life's work in science was his large book on this subject. He worked at it for eighteen years; it was published in 1600, only three years before his death. The title of the book is *De Magnete* ("magneticisque corporibus, et de magno magnete tellure, physiologia nova"). A copy of this large book, in Latin, is in the library of the Royal College of Physicians, London; and an English translation, by P. F. Mottelay, was published in London in 1893. Gilbert set forth in this book his great theory that the globe of the earth acted as an enormous magnet, or loadstone, and that this action accounted for the tendency of the magnetic needle to point in a polar direction. In his book he describes the numerous experiments on which he based his theory of terrestrial magnetism: he also considers the magnetic movements, the direction, variations, and dip of the magnet, and he adds a detailed account of magnets and loadstones

Gilbert also made numerous experiments by means of a loadstone ground into a globular form, having thus the shape of the earth. This globular loadstone he named a "terrella" or little earth. He placed magnetic needles on this "terrella," and made a large number of observations thereon. The results of these observations were similar to those noted with respect to the magnetic needle and the earth. And so the building up of his theory of terrestrial magnetism was aided by his observations on the magnetic needle and his "terrella"

Gilbert's book is devoted mainly to magnetism, but in one chapter (II) he deals with another subject, which has now become of such enormous importance in science and daily life In this chapter he describes a large number of phenomena which differ from magnetic phenomena It is said that Thales, who lived about 600 B.C., discovered that amber when rubbed acquires the power of attracting light bodies, such as pieces of pith or cork. Now Gilbert showed by his experiments that this attractive power could be developed by rubbing other substances besides amber He showed that wax, sulphur, glass, and many other substances, when rubbed with a piece of dry flannel, were then also able to attract small fragments of paper, cork, and other light bodies To this attractive power he gave the name of *electricity* (electricitas), from the Greek word for amber—ἤλεκτρον We thus owe to Gilbert the word electricity, and from this word numerous other terms have been derived Gilbert discusses the reasons for this attraction power, and excludes the views previously held He also compares and contrasts the attraction of electric and magnetic bodies The distinction between electricity and magnetism was therefore first established by Gilbert and the study of electrical science commenced with his work

Thus the foundation of the science of terrestrial magnetism and of electrical science was laid by Gilbert in his marvellous book It is full of original observations and records of experiments, and in it he demonstrated the value of experimental methods of investigation before Bacon's celebrated writings appeared At the end of the book Gilbert put forward views which he describes as a "new physiology" Some of these views are remarkable and interesting, especially in a work on physical science In this section of his book Gilbert remarks: "If there is aught of which man may boast, that of a surety is soul, is mind At a meeting of the Royal Geographical Society in 1903, to commemorate the reign of Queen Elizabeth, Professor Silvanus Thompson, in an

address on William Gilbert, describes him as the father of electrical science, and points out that before Gilbert there was no electrician.

Gilbert was successful in his practice, and was appointed physician to Queen Elizabeth, and afterwards to James I. In the town hall at Colchester is a painting, by Mr. Acland Hunt, representing Gilbert demonstrating his electrical and magnetic experiments to Queen Elizabeth and her Court. On the facade of the town hall is a statue of him, and in the public library a copy of his portrait. Gilbert's remains rest in Holy Trinity Church, Colchester, where a mural tablet tells briefly his life record. His monument, as Professor S. Thompson remarks, is his book in which he laid the foundation of terrestrial magnetism and of the experimental science of electricity. For this the world will always honour him, and medical men will be glad he was a physician.

R. T. WILLIAMSON.

Ireland

Vital Statistics for the Irish Free State

During the first quarter of the present year 14,301 births were registered in the Irish Free State. This number represents a birth rate of 19.4 per 1,000 of the estimated population, being 0.6 below the average rate for the first quarters of the ten years 1921–30. The equivalent figure for Northern Ireland was 20.6, and for England and Wales 16.3. Deaths registered during the quarter numbered 13,680, or a rate of 18.5 per 1,000. This rate is 1.3 above the rate for the first quarter of the previous year, and 1.1 above the average rate for the first quarters of the preceding decennium. Of the deaths registered, 1,271, or 9.3 per cent., were those of infants under 1 year, the number of deaths of infants being equivalent to 89 per 1,000 births, compared with 67, 52, and 71 for the three previous quarters respectively. The mortality in the Irish Free State from the principal epidemic diseases was higher than that for the first quarter of the preceding year, representing an annual rate of 0.7 per 1,000, compared with an average rate of 0.6 for the first quarters of the five years 1926–30. This higher death rate is attributed mainly to an increase in the mortality from measles, diarrhoea, and enteritis (of children under 2 years), and in a lesser degree to an increase in deaths from scarlet fever. Deaths from all forms of tuberculosis numbered 1,048, or an annual rate of 1.4 per 1,000 ; while the number of deaths ascribed to accidents and diseases of pregnancy and childbirth was 59, or a rate of 4.1 per 1,000 births registered.

Treatment of the Insane in Ireland

An attractive and detailed account of *The History of the Care of the Insane in Ireland up to the end of the Nineteenth Century* has now been published by Dr. T. Percy C. Kirkpatrick, registrar of the Royal College of Physicians of Ireland. The author opens with a brief account of the ancient views held about madness in Druidic times, and recalls that, during the codification of the ancient laws of Ireland about the time of St. Patrick, very definite regulations were defined for the protection of persons of unsound mind, provision being also made for their children. Later, monastic hospitals undertook the care of such patients, but after one or two abortive attempts at providing special institutions for them, the practice of confining dangerous lunatics in prisons continued until well on into the nineteenth century, though cells were provided at certain workhouses for them. St. Patrick's Hospital in Dublin was opened in 1757, and although very inadequate as regards accommodation, it had to suffice for the entire country for many years. At the beginning of the nineteenth century it was still the only public hospital exclusively devoted to the care of the insane, but a private asylum had been opened near Cork in 1799, and many insane persons were being maintained in the "Houses of Industry" of Dublin, Cork, Limerick, and Waterford. The Cork institution—which had been established in 1787—developed subsequently into one of the largest lunatic asylums in Ireland. The early years of the nineteenth century saw the birth of active interest in the treatment and classification of the insane, thanks mainly to Dr. Alexander Jackson, who concerned himself actively with the foundation of the Richmond Asylum in Dublin, and the private asylum at Farnham House. During the next forty years a great advance was made in the care of the insane, and various asylums came into existence in different parts of the country. This booklet, which is printed at the Dublin University Press by Ponsonby and Gibbs, represents a useful contribution to the history of what is now recognized as a definite branch of medicine.

Mayo Mental Hospital

In the annual report of the Mayo Mental Hospital for 1930 the resident medical superintendent, Dr. Sheridan, states that during the year 133 patients were admitted, 76 were discharged, and 73 died, the daily average number resident being 812. The most prevalent form of mental disorder was melancholia (recent), of which there were 33 cases, followed by dementia praecox (25). Other forms were: mania, 13 ; delusional (non-systematized), 9 ; recurrent mania and melancholia, mental deficiency, and senile dementia. Heredity was the cause or a factor in 29 cases, mental stress in 2, critical periods in 24, mental deficiency in 12, and alcohol in 6 cases. Other causes were bodily diseases—nervous, gastro-intestinal, and pulmonary. The number of discharged patients was below the average, the percentage of recovery on the number of admissions being 44.3. This was due chiefly to the unfavourable and relapsing type of cases under care ; also to the fact that many of the acquired forms of mental disease supervened on a condition of mental deficiency in some degree. Deaths numbered 73, or 8.6 per cent. of the daily average number. All deaths were due to natural causes. Phthisis and other forms of tuberculous diseases accounted for 20, respiratory and cardiac diseases for 13, atrophy and senile decay for 12. Other causes were malignant disease, exhaustion from mania or melancholia, and organic brain disease. Of the patients who died, 29 were about 70 years of age.

Scotland

New Edinburgh Chair

Through a grant from the trust fund of the late Mr. Edward Clark, printer, Edinburgh, a chair of child life and health, known as the Edward Clark Chair, was recently founded in the University of Edinburgh. The University Court has now appointed Charles McNeil, M.D., F.R.C.P.Ed., to be the first occupant of this chair. Professor McNeil was born at Stranraer, and was educated at George Watson's College, Edinburgh. He took the M.A. degree at Edinburgh in 1901, and graduated M.B., Ch.B. with first-class honours in 1905. After acting as resident physician to the late Sir Thomas Fraser in the Royal Infirmary of Edinburgh, he became resident for a time in the Royal Edinburgh Hospital for Sick Children, and house-physician to the East London Hospital for Children at Shadwell. In 1910 he became a member of the Royal College of Physicians, and Fellow in 1913. At present he is physician to the Royal Edinburgh Hospital for Sick

Children. During the war Professor McNeil served on the staff of the Scottish Red Cross Hospital at Rouen. He has made numerous contributions to medical literature on the occurrence of disease in early life.

Edinburgh Medical Graduation

The summer graduation ceremony of the University of Edinburgh took place in the McEwan Hall on July 22nd, under the presidency of the Vice-Chancellor, Principal Sir Thomas Holland, who conferred the degrees. It was announced that the Cameron Prize in practical therapeutics for the present year had been awarded to Madame Marie Curie, Paris, in recognition of the therapeutic results which had been made possible by her discovery of radium. The M.D. degree was conferred on eleven persons, and the degrees of M.B., Ch.B. on about 130. After the capping ceremony the graduates were addressed by the promoter, Professor D. Murray Lyon, who said he wished to take advantage of the opportunity to direct their attention to the claims of medical research. The large amount of information which was compressed into five years of medical study was far from being either complete or final. The late Sir James Mackenzie had remarked that the intelligent practitioner before he had been long in practice discovered that he was unable to recognize the ailments of the great majority of his patients, and that many of the aspects of their illnesses had never been presented in his hospital training. Medicine had become one of the most complex of the sciences, although it still remained largely an art. Although the general death rate had been reduced by one-half in the last two hundred years, the cause of cancer remained unknown, while organic disorders of the kidneys and blood vessels were still responsible for much ill-health, and at intervals the country was swept by epidemics of influenza, as yet beyond control. There was a tradition in medicine that no discovery could be kept secret for the advantage of an individual, any advance being at once made public so that the new knowledge became available to all. The individual who made a contribution to medical knowledge derived no personal gain, though his success might favour academic promotion. Some years ago Parliament had encouraged investigation by a grant administered by the Medical Research Council, and this had been of great assistance; much more, however, was required.

England and Wales

Mental Deficiency

The annual report of the Board of Control, to which reference has been made in recent issues, states that the total number of mentally defective patients resident in institutions and under guardianship on January 1st, 1931, in England and Wales amounted to 30,354. On the mental deficiency side the question of accommodation again assumes a place of primary importance. Three new institutions have been opened during the year, and these, together with changes at other institutions, have provided 1,255 new beds. A number of local authorities are taking active steps to provide accommodation for mental defectives, but the need for further provision is still acute. The Board reports that it has received the recommendations of a special committee, under the chairmanship of Mr. Walter Hedley, K.C., which was appointed to advise on the requirements of colonies for mental defectives. This committee states that "the supervision exercised by the Board of Control in regard to the expenditure on colony schemes has been effective, and we find it very difficult, even after close scrutiny, to cut their requirements much finer." At the same time the committee makes valuable suggestions which will, it is hoped, conduce to further economy in construction. The Board observes that there has been a steady fall in the cost per bed, and that recent contracts indicate that the cost of construction, excluding the cost of land, may now be taken as slightly exceeding £300 a bed for a complete colony. A point of considerable interest arises in connexion with the provision of these colonies. The Board again draws attention to the difficulty of finding superintendents with any real experience of mental deficiency work for the new colonies which are being established, and it emphasizes the importance of devising means by which these officers may familiarize themselves with modern methods of handling and training defectives. On the controversial issues of marriage and sterilization the Board repeats the view previously expressed that the marriage of defectives under order should be prohibited by law. As regards sterilization it observes that the question deserves close and scientific study, but that the necessary data are not yet available to enable any judgement to be formed on the social and physical consequences of legislation legalizing sterilization.

Birth Control Clinics

Reference was made in this column on April 4th (p. 600) to the memorandum on birth control clinics issued by the Minister of Health in March last. Finding that misconceptions have arisen in regard to the views therein expressed, the Minister now brings certain matters to the notice of local authorities in Circular 1208, dated July 14th. This emphasizes the point that the Government is advised that local authorities have no general power to establish birth control clinics as such. The memorandum was issued solely for the purpose of explaining the views of the Government on the use of institutions controlled by local authorities for the purpose of giving advice to women on contraceptive methods, and the question of providing facilities for giving such advice within the limits laid down in the memorandum is a matter entirely within the discretion of the local authority. Under the Maternity and Child Welfare Act, 1918, the powers of local authorities are limited, so far as women are concerned, to making arrangements for attending to the health of expectant mothers and nursing mothers. If an authority decides to provide facilities for giving birth control advice at a maternity and child welfare centre their use must be strictly incidental to the purpose for which the centre is established, and they can be made available only for married women who are either expectant or nursing mothers already in attendance at the centre and in whose cases further pregnancy would be detrimental to health. If action is taken under the Public Health Acts to establish a clinic at which medical advice and treatment would be available for women suffering from gynaecological conditions, the use of any facilities provided at the clinic for giving advice on contraceptive methods must be strictly incidental to the purpose for which the clinic is established—namely, the treatment of sick persons. Only women who need medical advice and treatment for gynaecological conditions can properly be admitted to the clinic, and contraceptive advice can properly be given only to married women in attendance at the clinic in whom pregnancy would be detrimental to health. It is obviously desirable for a local authority to obtain the services of an officer specially experienced in the clinical advice and treatment needed at a gynaecological centre of this sort. The Minister does not consider it desirable that a gynaecological clinic should be established at a maternity and child welfare centre, and if an authority is satisfied that there is need for such a clinic it should be provided in separate premises or at a hospital. Expectant and nursing mothers in attendance at such

centres who are found to need medical advice and treatment for gynaecological conditions could then be referred to the clinic. The Minister considers it important that no existing officer of a local authority should be prejudiced in any way by a decision of the authority to provide facilities for birth control advice within the limits laid down in the memorandum. He is of opinion that this work should not be regarded as falling within the scope of the normal duties of the medical officers of a local authority, who should be free to undertake it or decline it.

Out-patient Clinics under Mental Treatment Act

Out-patient clinics for persons suffering from mental disorders have been established at three general hospitals under the management of the London County Council—namely, St. Mary (Islington), St. Charles' (Notting Hill), and the Mile End Hospital. They have been in operation since early in May, and a very useful work has been begun, which is believed to be susceptible of development on larger lines. The clinics are under the general direction of the medical superintendent of the Maudsley Hospital, and a medical officer from the staff of that hospital has been detailed to act at each clinic. It is hoped to attach medical officers from other mental hospitals. Students from the London School of Economics who have been receiving practical instruction at the Maudsley Hospital as part of a mental health course have voluntarily given their services at the associated out-patient clinics as social workers to secure information essential to the medical officer in dealing with his patients. This arrangement, however, cannot continue after the end of July, when the students who have finished their course will be replaced by beginners unable for a time to give useful service. The London County Council, therefore, proposes to employ one psychiatric worker, trained in scientific methods, to serve all three clinics, and to be attached to the staff of the Maudsley Hospital.

Correspondence

PLUMBISM

SIR,—I have just been reading with the greatest interest the two instructive and valuable papers on lead poisoning in the *Journal* of July 18th, by Dr. Edwin Bramwell and Dr. Norman Porritt. On first reading these communications it seemed as though every possible source of the poison and its mode of entry had been exhausted; but yet there is another which, in my knowledge as a doctor practising in a rural district in Wilts whose experience goes back to 1871, was the cause of more than 50 per cent. of the many scores of cases of plumbism which I was called upon to treat. The cause I allude to is the drinking of "home made" wine fermented in a red glazed pan; the glaze for these utensils was made from a lead compound, but it was readily dissolved by the acid of the fruit, with which it was in contact for some days. The cottagers nearly always had good gardens, and grew quantities of fruit, such as gooseberries, currants, rhubarb, plums, and in a few cases even grapes were to be seen on their walls. Parsnips and elderberries, though much used, did not seem to be such great offenders—probably from having less free acid in their contents. I found after some years, on a few occasions, where it was possible to exclude every kind of wine (and, of course, other recognized sources), that the same consequences ensued from the drinking of ginger-beer made with lemons and ginger and sugar, and fermented in a red glazed pan. The symptoms were of the acute kind—abdominal pain, much vomiting, obstinate constipation, a sallow complexion, yellowish conjunctivae, and the blue line on the gums. I noted also one other very easily overlooked source of the poison. A cider press with a leaden tray to catch the expressed apple juice went round to many farms in the district, and left in its trail many blue lines, yellow eyes, and much stomach ache!—I am, etc.,

R. LEWIS WILLCOX, M.R.C.S., L.R.C.P.

Salisbury, July 20th.

SIR,—I was much interested to see the papers on plumbism contributed to the *Journal* of July 18th by Drs. Bramwell and Porritt, as for a considerable number of years I have been studying this question in my own area.

I am in thorough agreement with Dr. Porritt that there are two types of plumbism—that is, a classical type, which is quoted in textbooks, and a mild and insidious form, which very often escapes notice, and which may only be found out by a sudden exacerbation of symptoms. I have noticed the following types of illness occur, due to the taking of minute quantities of lead:

Marasmus, wasting, and general debility in young infants.
Premature birth, and congenital debility in infants.
Infantile convulsions.
Neuritis of various forms.
Diarrhoea.
Constipation.
Mental depression and, in one case, encephalitis.
Severe anaemia, followed by death.
Abortion.
Epileptiform convulsions in adults.

During last year the infantile mortality rate, in an area I know of, supplied with a very lead-soluble water, was 134, while that of an area in the same district in which the water had been treated to prevent lead solubility was 56; the following causes of deaths were noted among children in the lead-soluble area:

1. Prematurity.
2. Infantile convulsions and infantile enteritis.
3. Convulsions and enteritis with jaundice.
4. Prematurity.
5. Epileptiform convulsions } Twins both died within four-
6. Inanition } teen days after birth.
7. Prematurity.

In this area lead is found in the water supply of every house in which there is a lead pipe, and in Cases 5 and 6 the mother had been living, just up to confinement, in a house in which the amount of lead in the water was found to be 0.47 grain per gallon, or nearly 1/2 grain per gallon. I see Dr. Porritt found that 1/14 grain could cause symptoms. In this particular supply nearly all the samples show an amount of lead greater than 1/10 grain, and some as much as 3/4 grain per gallon. I might state that this supply is being dealt with, and a filtration and dosing plant will be installed very shortly to prevent the action of the water on the lead pipes, so that the residents in this area in future will have an exceedingly pure supply, because the water itself is of a most excellent quality (prior to going into the pipes).

For a number of years an investigation of the water north-west of Derbyshire was carried out by Dr. Thresh and myself, details of which will be found in the book, *Examination of Water Supplies*, by Thresh and Beale. In this investigation we found that it was the length of water-service pipe that was the determining factor in causing large amounts of lead to be dissolved, rather than the pressure of water. We came to the conclusion also that 0.05 part per 100,000 of lead was the largest amount that could be taken with safety, and also that silicate of soda was effective in some instances in preventing lead solubility. I am inclined to think, however, that the addition of lime to the silica would render it more effective.

Dr. Porritt mentions lead as being the cause of maternal mortality. I thoroughly agree with him, and I would like to suggest that in those districts with a high maternal and infantile mortality in which there is any suspicion of the water being lead-soluble the supply should be examined for the presence of lead (that is, supply from the tap).—I am, etc.,

ERNEST MILLIGAN, M.D., D.P.H.,
July 20th. M.O.H., Glossop and Glossop-dale.

AFTER-EFFECTS OF IRRADIATION OF UTERUS

SIR,—I was interested to read the letter from Mr. R. S. Pilcher in your issue of July 18th (p. 122). I hope sincerely that University College Hospital, which has done such good work on the problem of creating artificial menopause, will continue to follow up its cases, as in ten years' time such figures will be of real value in the question of radium treatment as prophylaxis for carcinoma of the cervix uteri.

It is difficult to follow Mr. Pilcher's suggestion that in the case quoted the radium was responsible for a malignant cyst of the ovary. Surely the most that he can argue from this one case is that the irradiation will not prevent the growth of an ovarian cyst, and a malignant one at that. I have myself seen an ovarian cyst arise some time after irradiation, but fortunately it was not malignant.—I am, etc.,

London, W.1, July 22nd. MALCOLM DONALDSON.

IMMUNITY AND MALIGNANT TUMOURS

SIR,—I notice in Dr. Thomas Lumsden's paper entitled "Tumour immunity; the effects of eu-globulin and pseudo-globulin fractions of anti-cancer sera on tissue cultures" (*Journ. of Path. and Bact.*, 1931, iii, 349) he states that serums, made by repeated inoculation of human breast cancer into a sheep, kill cancer tissue cultures. He associates this action with the euglobulin of the anti-cancer serum, and concludes that "the euglobulin fraction contains all the antibodies which are specifically toxic to cancer cells." He considers that his many experiments demonstrate "beyond doubt the existence of antibodies having a specific affinity for cancer cells."

Now the bactericidal property of immune serum in bacterial infections, as usually interpreted, depends on two substances acting together—amboceptor and complement. The amboceptor resists heat, and the complement is thermo-labile—thus resembling an enzyme.

Dr. Lumsden prepared his anti-cancer serums (and others) by the method I described in 1913 at the Therapeutic Section of the International Congress of Medicine—namely, by inoculating human breast cancer repeatedly into a sheep or other animal. He attributes the destructive effect he obtained to the action of the "euglobulins (and pseudo-globulins) *plus* complement." As stated, "the isolated globulins are re-dissolved in the appropriate fresh normal serums. The fresh normal serums supply the complement which is required in all these reactions." He omits any reference to my previous work, and does not allude to any part that might be played by ferment action in immune processes as applied to cancer (as mentioned in my letter in the *Journal* of April 25th). May I be allowed, therefore, to add some further remarks, and to suggest that induced ferment action, in my opinion, is the important factor in the destruction of mouse and human cancer in Dr. Lumsden's tissue culture experiments?

In the *British Medical Journal* (1927, i, 78), and in a publication in 1912, by analogy with bacterial infections I compared the activators in cancer serum, cancer extracts, and filtrates in their activating effect on lipase, with amboceptor and complement. In this connexion I found in 1909 that cancer serous fluid (oedema) from the arm of a patient, as well as cancer serum, increased the action of lipase in pancreatic extracts. Normal and cancer serum, and cancer extracts, activated *inactive lipase* in pancreatic extracts, separated from its *co-enzyme* by Rosenheim (1910). I also showed activation on inactive lipase (prolipase) of human pancreatic juice, which was obtained (1912) from a fistula of a pancreatic cyst involving the duct.

If bactericidal serum made by immunizing an animal against bacteria is heated, its power to kill the organism is lost. If normal serum is now added to the inactivated heated immune serum the mixture again becomes bactericidal.

In 1915, in my paper on the action of serum on the lipase of pancreatic juice (*Journ. of Physiology*, xlix. 4, 216), I described that (1) lipase activity in pancreatic juice, carefully collected, was always low; that (2) if one portion of the fresh juice was taken and heated it was rendered inactive—that is, it had no action on fats; and that (3) when the other portion of the fresh juice was added to the portion inactivated by heat the mixture became markedly more active than the original juice. In this process the heated portion of the juice or activator may be compared to the amboceptor in the heated bactericidal serum, and the untreated portion (fresh juice) or *prolipase* to normal serum. Thus, in this I showed the similarity of the mechanism of lipolysis to that of bacteriolysis. Further, in my table of cases I showed (1) that normal blood serum, whether heated or not, could replace the heat-inactivated portion of pancreatic juice; (2) that this activating property of the serum was distinctly lessened in persons suffering from cancer, and in the acute stages of infectious diseases; and (3) that in two patients who recovered from inoperable cancer the lipase-activating *titre* of the blood serum, as previously demonstrated with human pancreatic juice, from being distinctly lowered before treatment, was markedly raised above normal. At the same time the anti-tryptic power of the serum was definitely reduced to normal or subnormal.

I have more particularly referred to these experiments because, though the separation of pancreatic juice into two parts at the time was considered a surprising result, its bearing on the problem of immunity and in relation to cancer seems to have been lost sight of.

According to the above view, in Dr Lumsden's experiments the activator (or activators) contained in the added normal sheep serum, which by itself does not split fats, may be expected to activate the lipase in the cancer cells of the cultures, with digestive action on the fat content of the cancer cells (with fatty acid products), and rapid destructive effect on the cancer cultures. The lipase (with other intracellular enzymes) in cancer cells has long been known. "Euglobulin, which belongs to the same class of serum proteins or globulins as fibrinogen," as I have stated, "is one of the agents I have found in conjunction with Dr. A. Sykes (Physiological Laboratory, King's College, 1911) which increases the lipolytic or fat-splitting ferment *in vitro* and *in vivo*, with marked increase of weight of the animals (normal mice). Cancer extracts and filtrates, heated and unheated, have activating properties on lipase, though less than normal tissue extracts, so that the activator in the cancer cells of the cultures conversely may activate the proenzyme complement contained in the added normal fresh sheep serum.

Dr. Lumsden states that "The presence of fat granules in cultured cancer cells . . . represents merely the storage of food material." The view long held is that in cancer

cells there is an excess of fats, lipoids, and phosphorized fats (lipins)—for example, lecithin. Lecithin, I found, is split by lipase—as others had previously shown. The Liverpool research workers, I have reason to believe, have found more recently that there is an absolute increase in the phospholipins—for example, lecithin content of cancerous cells.

These fats and lipins (phosphatides), as I mentioned in the *British Medical Journal* (August 11th, 1923), are soluble in the usual solvents and have antigenic properties. The introduction of them, as well as of proteins and other normal or specific co-enzymes or activators, into the blood activates the prolipase which is common to all tissues.

The importance of the demonstrated facts, and of ferment production and action, as factors in immunization, lies, as it seems to me, in their application to clinical work.

Alcohol, ether, and chloroform extracts of cancer tissue, with or without saponification, have long been prepared and employed by me, not only in diagnostic methods in cancer, but advocated in treatment, in addition to the normal fatty acids (soaps). Similar preparations were made from tuberculous tissues and tubercle bacilli for therapeutic use, and suggested also from other pathological tissues.—I am, etc.,

J. A. SHAW-MACKENZIE, M.D.Lond.

London, July 16th.

RAISED BLOOD PRESSURE

SIR,—Professor Hay's admirable lecture tempts one to ask whether it is not possible to amplify it by the preparation of a gramophone disk recording the sounds heard with the stethoscope, with a commentary demonstrating, among other things, the point at which the diastolic reading should be taken.

There are several different teachings on this point, and even in normal cases the sequence of the sounds is not always the same. This makes it difficult to compare one observer's results with another's, and it also leads to trouble with insurance companies in life examinations. Some societies, accustomed to one method, will inquire why the diastolic pressure reads so high, while other societies will pass it.

If a record could be made including the more common sequences of sounds (not omitting the case where there is no sequence at all, but the sounds simply fade away as the pressure gets lower), and emphasizing the diastolic point, it would be extremely valuable to many practitioners who are no longer in daily contact with the schools, and who wish for some definite standard to refer to.—I am, etc.,

Leigh, July 25th. JOSEPH JONES, M.D.

SIR,—The remarks made by Dr. Pines in his letter on this subject in the *Journal* of July 25th are of much interest and importance. It is quite true that diagnosis of the condition is often first made with the ophthalmoscope; but, on the other hand, in well-marked cases ophthalmoscopic examination may be negative.

I should be very grateful if Dr. Pines would let us know what signs he finds ophthalmoscopically at an early stage. Gross changes—such as haemorrhages, nipping of veins, silver-wire arteries—anyone can see; and when they are present the signs are obvious without the use of an ophthalmoscope. Would it be correct to say that long before the walls of the retinal vessels are visible (normally only the blood column being seen) the sign that has to be depended on is a narrowing of the lumen of the arteries, and that this is not always capable of being recognized with certainty?—I am, etc.,

Stoke-on-Trent, July 25th. W. DUNCAN LAWRIE.

REFRESHER COURSES FOR SHIP SURGEONS

SIR,—Having been a ship surgeon for more than ten years, I read with interest the communications of Dr. Haslett Frazer (*Journal*, June 27th, p. 1139) and of Dr. T. Gwynne Maitland (July 18th, p. 123) on the refresher courses for ship surgeons.

Dr. Maitland has the advantage of being in a position to see things from both the ship surgeon's point of view and that of the owners, having had several years of sea-going experience, and being now medical superintendent of one of our most important shipping companies. To my mind Dr. Maitland, without waste of words, has proved the necessity for these post-graduate studies put forward by the British Medical Association; but I cannot help feeling more than a little sympathy with Dr. Frazer's plea for a course of practical experience in emergency operative surgery, particularly dealing with the acute abdomen. Dr. Maitland does not deny that urgent operations should be performed at sea; but I cannot help thinking that the inexperienced or timid ship surgeon, on reading Dr. Maitland's letter, may be led to persuade himself that all operations are best left alone until the patient can be taken to hospital ashore. The most inexperienced surgeon should take heart, and remember that operation done in time, even in the crudest hands, will give good results in imperative cases, in which delay until the case is placed in most expert hands ashore will result in almost certain disaster. One of our greatest difficulties, on the rare occasion where operation is required, is to get a satisfactory anaesthesia; here familiarity with the spinal method would be a great advantage. It is most important, above all for ship surgeons, as Dr. Maitland points out, to be able to recognize when operation is imperative and when a case can be left for shore hospital. If a refresher course could instil this vital matter thoroughly into the ship surgeon's mind it would have justified the trouble taken, and time would not be wasted.

With regard to the diagnosis of the exanthemata and various forms of conjunctivitis, these present no greater difficulties to a ship surgeon as such than they do ashore. On the North Atlantic nowadays, with the curtailment of emigration and previous examination ashore, one rarely or never sees a case of trachoma or of other serious form of conjunctivitis. As for ship hygiene, shipping Acts, and quarantine procedure, most ship surgeons know the quarantine procedure from experience; but the embryo ship surgeon would benefit by instruction in this matter. It must be admitted by a great many of us that we know precious little about ship construction, and are therefore not in a position to give expert opinion with regard to ventilation, water, food storage, etc.; hence the justification for inclusion of ship hygiene in the special courses. I do not agree with Dr. Frazer that one rarely sees tropical diseases on board ship; any surgeon on a ship which cruises in the Tropics (a common occurrence nowadays) should have a fair knowledge of the commoner tropical diseases that he may be called on to treat. I have seen surgeons very puzzled by a large number of dengue fever cases, both in the East and West Indies; they had never seen dengue cases, and consequently were at a disadvantage in the prognosis of their passenger patients, who become more anxious about themselves at sea. Amoebic and other dysenteries, sprue, and malaria—to mention only a few of the diseases commonly associated with the Tropics—are ordinary occurrences, and even cholera sometimes makes its appearance, so that no excuse seems necessary for including tropical diseases in the post-graduate curriculum. I was glad to read of Dr. Frazer's experience of venereal disease at sea, and must pay a tribute to the clean living of

members of the crews of various ships on the North Atlantic trade. It will surprise readers to learn that in ten years I have not seen more than a dozen cases of venereal disease at sea, and those included passengers as well as crew, all members of which are examined every voyage.

Dr. Frazer's suggestion of a six months' house-surgeoncy is a good one, if we could obtain the necessary positions. The managers of all big shipping companies are quite aware that much is expected of the ship surgeon by the travelling public of to-day, and are more than generous, in normal times, in arranging the necessary leave for post-graduate work, encouraging their surgeons to keep up to date with modern teaching in all branches of our profession.—I am, etc.,

London, July 24th. J. T. BRENNAN, F.R.C.S.I.

EPIBLASTIC DEFECTS

SIR,—Dr. Rutherfurd's article in the *Journal* of July 4th upon certain dental defects stimulates me to record the following case. My patient is a boy aged 3 years and 4 months. A full-term child, he appeared perfectly normal at birth, but he did not thrive for the first few weeks of life. At 2 months, however, he was average in weight and healthy, and continued normally in every respect, except as regards his teeth and hair. His first teeth did not appear until he was 2, when two fang-like teeth erupted in the position of upper lateral incisors. They are now long, very sharply pointed, strong teeth, with a marked antero-posterior curve. As no more teeth erupted during the next six months an *x*-ray photograph was taken, and revealed six more teeth—four upper and two lower molars. At the age of 3 the posterior upper molars erupted without difficulty, since when there has been no change in his condition. His hair is extremely scanty and of lanugo type, and is less than an inch long. Dr. Rutherfurd notes that absence of sweat glands has been recorded in this type of case; this child has never been observed to perspire, and certainly did not do so, despite the heat of the weather, during a sharp attack of asthma. Two preceding generations, all without trace of this defect, are traceable in this case, and two older brothers have normal dentition.—I am, etc.,

Newcastle-on-Tyne, July 15th. IAN E. MCCRACKEN, M.D.

BURST PILCHER'S BAG

SIR,—Dr. Hefferman's account, in the *Journal* of July 18th, of the extraction of a broken catheter from the urethra and bladder reminds me of a similar incident which occurred in connexion with a Pilcher's bag, used to prevent haemorrhage following prostatectomy. The bag, being old, burst *in situ*, and was pulled by the extension weight down the urethra, where it stuck just beyond the membranous portion. Efforts to pull it out resulted in both the attached pieces of rubber (one through the suprapubic wound, the other through the urethra) breaking off just at their junction with the bag. With manipulation and sinus forceps introduced up the meatus, we eventually managed to pull the offending item down to the meatus, where it stuck for twenty minutes, and eventually had to be released by a meatotomy, done under local anaesthesia. The patient, who rendered us every possible assistance in his awkward and painful predicament, was none the worse, and still treasures the bag, which we allowed him to keep.—I am, etc.,

Birmingham, July 18th. J. C. HAWKSLEY.

BROKEN CATHETER IN URETHRA

SIR,—I was interested in Dr. Hefferman's memorandum (July 18th, p. 104) describing a case of a catheter broken off in the urethra. I have had a similar case. The patient was an old man, who was occasionally troubled with retention of urine, due to prostatic enlargement. He kept a rubber catheter in a cupboard, with his cigars, over the fireplace. After a birthday dinner, on a cold night, he had to use the catheter, which had become quite hard, and which broke off in the urethra. He failed to extract it, and came to hospital with three broken fragments in the urethra. I extracted them with a pair of "crocodile" forceps, which were pushed into the lumen of the catheter, a finger being placed in the perineum to prevent the broken fragments slipping backwards. When both blades of the forceps were inside the catheter the forceps were opened and gripped the fragment (from inside), so that it was removed easily without any damage to the mucosa.—I am, etc.,

R. K. DEBENHAM, F.R.C.S.

Selly Oak Hospital, Birmingham, July 22nd.

Obituary

F. H. G. HUTCHINSON, C.I.E., M.B., C.M.

Major-General I.M.S. (ret.)

We regret to announce that Major-General Francis Hope Grant Hutchinson, C.I.E., Indian Medical Service (ret.), died at Bedford on July 25th, aged 60. He was born on October 28th, 1870, the son of the late Surgeon General J. A. C. Hutchinson, I.M.S., and was educated at Bedford and at Edinburgh University, where he graduated M.B. and C.M. in 1892. Subsequently he took the diplomas of D.T.M. and H., and D.P.H. at Cambridge in 1907. After filling the post of house-surgeon at the Cheltenham General Hospital from 1893 to 1896, he entered the I.M.S. as surgeon lieutenant on July 28th, 1897, attained the rank of colonel on April 19th, 1924, and of major-general on April 1st, 1926, retiring on April 3rd, 1929. His first few years' service were spent as medical officer of the 5th Bombay Cavalry, the Sind Horse. In 1906 he entered civil employ in the sanitary department as deputy sanitary commissioner in the Bombay Presidency. In 1913 he became sanitary commissioner of Bombay, and in 1919 public health commissioner with the Government of India, and on promotion to major-general was posted as surgeon general to the Government of Madras. He served in the China war of 1900, receiving the medal. He received the C.I.E. on January 1st, 1922, and on October 1st, 1926, was appointed Honorary Surgeon to the King.

After his retirement General Hutchinson joined the Council of the British Medical Association as representative of the Indian Medical Service, but had been in very bad health since he returned to England. He was also a member of the Naval and Military Committee in 1930-31. In 1899 he married Eileen FitzGerald, second daughter of Colonel G. H. W. O'Sullivan, late R.E., and leaves a widow, three sons, and two daughters.

By the death of Dr. PERCY ROSE, who passed away in a nursing home at Barnet on July 18th, the Stratford Division loses one of its most zealous and active workers in the cause of medical organization and advancement. Born in London, and educated at Christ's Hospital, Percy Rose received his medical training at Guy's. He qualified in 1887 and shortly afterwards settled in Canning Town, where he remained in practice for forty-four years, and only retired from work during the last three months. His first experience of public work was as a member of

the West Ham Board of Guardians, but it was during the 'nineties, when there was a general ferment in the ranks of medical practitioners dissatisfied with the condition of practice that he and a few other medical men founded a local medical society. This society was primarily medico-political in character, and sent a delegate to the Manchester conference, which later led to the reform of the British Medical Association and the creation of the new Divisional units, and the Annual Representative Meeting came into existence. Dr. Rose acted as the representative of the Stratford Division until the end of 1912, and was a member of the Contract Practice Subcommittee, when this committee was dealing with the National Insurance Bill. In recognition of his unselfish services the Stratford Division presented him with a gold watch and chain. Another question in which Dr. Rose interested himself was the payment of doctors called in to assist midwives, under the Midwives Act. In a paper contributed to the *Lancet* in 1904, he drew up a scale of fees for the different emergencies which might require medical assistance, and advocated that the local authority should make itself responsible for these fees. He could not carry his point then, but later, during the war, the Central Midwives Board found it necessary, owing to the scarcity of doctors, to adopt this plan. During the great war, though no longer of military age, Percy Rose offered his services to the R.A.M.C. and served with the forces for three years, with the rank of Captain.

The death took place, on July 15th, at his residence in Somerset Place, Glasgow, of Dr. JAMES GALBRAITH CONNAL, one of the oldest throat specialists in the country. Born in 1859, he graduated M.B., C.M. at Glasgow in 1886, and joined the Royal Faculty of Physicians and Surgeons, Glasgow, in 1900. For many years he was surgeon to the Glasgow Ear, Nose, and Throat Hospital, and lecturer on aural surgery in the Anderson College Medical School, contributing numerous papers dealing with the clinical aspects of his subject. Dr. Connal was vice-president of the Section of Otology at the Annual Meeting of the British Medical Association in 1922.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

The adjournment of the House of Commons for the Summer Recess was arranged for July 31st. During the week the House discussed the Estimates for the Mines Department, the Home Office, and for the health services. In the last-named debate, on July 29th, discussion was expected on the Poor Law, vaccination, dumps, health insurance, mental deficiency, and the utilization of research. A vote for salaries and expenses of the Ministry of Health was carried on July 28th without debate.

The Bethlem Hospital (Amendment) Bill passed through committee and was reported to the House of Commons on July 28th.

A resolution calling for Government legislation to regulate the disposal of London refuse has been signed by members for London and the Home Counties.

On July 27th, on the motion of Mr. Short, a return was ordered to be prepared showing the number of experiments carried out under licence on living animals in 1930.

The House of Lords also sat this week, and adjourned for the Recess.

Cerebro-spinal Fever

Mr. TURBERVILL asked Mr. T. Shaw whether the junior division of the Officers' Training Corps had been compelled this year, and, if so, for what reason; and whether, owing to the continued prevalence of cerebro-spinal meningitis throughout the country, he would collect boys of a susceptible age from the camp.

Mr. SHAW replied: Boys who would have attended camp but for the cancellation would, for purposes of "efficiency," be deemed to have attended.

On the same day Mr. SHAW told Mr. Marjoribanks that the number of deaths from cerebro-spinal meningitis in the British Army at home during the years 1928, 1929, and 1930 was 2, 9, and 10 respectively.

On July 27th Miss LAWRENCE gave Dr. Fremantle provisional figures, relating to civilians only, of the number of cases of cerebro-spinal fever notified in England and Wales in the four weeks ended July 18th last. These figures showed that for the week ended June 27th there were 41 cases; for the week ended July 4th, 39 cases; the week ended July 11th, 43 cases; and the week ended July 18th, 43 cases. Of these 166 cases, 72 were notified in the West Riding of Yorkshire and 22 in Lancashire. Dr. FREMANTLE asked if Miss Lawrence thought that, as a result of these figures, it was advisable to stop the congregation of people on their holidays. Miss LAWRENCE said she drew no such conclusion. Dr. FREMANTLE asked if the Minister had advised the War Office to cancel camps in consequence of this disease. The question was not answered.

On the same date Mr. WESTWOOD informed Dr. Fremantle that the numbers of cases of cerebro-spinal fever notified in Scotland during the past four weeks were: week ending June 27th, 11; week ending July 4th, 5; week ending July 11th, 13; and week ending July 18th, 6. Of these 35 cases, 19 were notified in Glasgow. Dr. FREMANTLE gave notice that he would raise the matter on the discussion on the Appropriation Bill.

Mr. SHAW assured Mr. Marjoribanks, on July 27th, that every precaution was being taken against meningitis in the Army at home. Special precautions had been taken in sterilization of utensils and ventilation, against overcrowding, and, above all, to the persons who were suspected of being carriers of the disease. He did not think there was need to make special provision in the permanent buildings of the Army.

Certification of Insured Persons

Replying to Mr. Lewis, on July 23rd, Mr. GREENWOOD said steps to ensure that medical practitioners only issued certificates of incapacity to insured persons who were genuinely unable to work by reason of sickness had been taken by the amendment of the Medical Benefit Regulations and by the issue of a memorandum on certification to all insurance doctors. The object was to ensure that claims on the funds of approved societies were not supported by medical certificates in any case in which the claimant was not incapable of work. Mr. LEWIS asked Mr. Greenwood to provide that the cost of sickness visitation undertaken by approved societies should be borne out of the funds payable by approved societies towards the cost of medical treatment, until such time as he was satisfied that medical practitioners were issuing certificates strictly in accordance with the regulations. Mr. GREENWOOD said the suggestion appeared to be based on the assumption that sickness visitation was required solely as a check on medical certification, and he could not promise to consider it favourably. Mr. LEWIS asked if additional supervision was asked from the societies on account of increased sickness. Mr. GREENWOOD replied that this might be so, but he did not accept the assumption that in consequence there was need for increased visitation.

British-made Instruments

In reply to Mr. Hannon, on July 16th, Mr. GREENWOOD stated that the expenditure on surgical instruments and appliances by his Department for the last financial year amounted to £337, of which £62 was for foreign instruments. It was the policy of the Department to purchase British-made instruments whenever they could be obtained in this country at a competitive price and of a comparable quality. He had no information as to the expenditure incurred by local authorities for this purpose, but had requested them to make use to the utmost extent practicable of goods and materials of home production.

In reply to another question by Mr. Hannon, on July 16th, Mr. SHAW said that, during the year ended March 31st, 1930, £4,428 was spent on the purchase of surgical instruments and appliances by the Army, and this total included £18 of foreign

Stoke-on-Trent, July 25th.

equipment. Mr. AMMON told Mr. Hannon that the sum expended by the Admiralty on surgical instruments and appliances during the financial year 1930 was £4,400, of which less than £60 was for foreign instruments. It was the policy of both departments to buy British-made instruments.

Mr. MONTAGUE, replying to Mr. Hannon, on July 21st, said that during the year ended June 30th last the amount expended by the Air Ministry on surgical instruments and appliances was £1,410, of which £96 was in respect of foreign-made articles. It was the policy of the department to purchase British-made instruments whenever they were of suitable quality and could be obtained at a competitive price.

Capital Punishment

Mr. CLYNES told Mr. Rhys Davies, on July 22nd, that only one person under 21 has been executed in England and Wales during the last five years. Five persons have been executed in England and Wales since the Select Committee on Capital Punishment presented its report. Nineteen persons have been executed in Scotland since 1900. From January to June, 1931, eight persons in England and Wales were sentenced to death and three executed.

Mr. Clynes does not see his way to propose legislation to give effect to the recommendation that capital punishment should be suspended for five years. This was made by the Select Committee on the subject.

From 1921 to 1930 34 males and 46 females, who had been found guilty of murder but insane, were released from Broadmoor Criminal Lunatic Asylum.

During the five years 1925 to 1929, in England and Wales eight women were sentenced to death and one was executed; 35 charged with murder were found guilty but insane; 3 were found insane before trial and 24 insane on arraignment.

Mr. CLYNES told Colonel Moore, on July 23rd, that during the years 1924 to 1929 110 women were proceeded against for, or were convicted of, infanticide. In reply to Mr. LOVAT-FRASER, on the same date, Mr. CLYNES stated that during the five years following the passing of the Infanticide Act, 1922, two women convicted of infanticide were ordered by the court to be sent to institutions for mental defectives.

Mr. SHORT, replying on July 27th to Mr. Sorensen, said that no case could be traced in which a person sentenced to death in England and Wales between 1925 and 1929 had been reprieved solely on the ground that he was suffering from mental deficiency. In various cases a degree of mental instability was considered, with other grounds, in advising commutation.

Street Noise

Miss LAWRENCE told Mr. Freeman, on July 22nd, that the effects of noise and vibration were still under investigation by the Industrial Health Research Board. The Minister of Health did not see a need for a special inquiry on the lines of the Commission of Health of New York upon city noise, into the injury done to public health by noises such as riveting, pneumatic drills, motor horns, and steam whistles. Mr. HERBERT MORRISON, in an answer on the same day to Mr. Freeman, said he was not aware of any evidence that the fumes emitted by motor vehicles of any type in their ordinary use on the highways were a danger to public health. Progress had been made in reducing vibration from motor vehicles by the use of pneumatic tyres and by improvement of road surfaces.

Street Accidents in London

During a discussion on the Ministry of Transport Estimates, on July 23rd, Mr. HERBERT MORRISON said that in the first quarter of 1931 fatal and non-fatal highway accidents in the Metropolitan Police area decreased by 10 per cent., compared with the previous period. The Road Traffic Act and the Highway Code were producing results.

Midwifery Fees

On July 23rd Sir ERNEST GRAHAM-LITTLE asked Mr. Greenwood if he knew that the provision in the Midwives and Maternity Homes Act, 1926, requiring claims to be sent in by medical men for their fees within two months from the date of attendance on patients inflicted hardship on medical men who sent their accounts out only twice annually. Mr. GREENWOOD replied that representations on this matter were made to the Departmental Committee on the Training and Employment of Midwives, whose report included a recommendation on the subject. The question would be borne in mind in any legislation for the amendment of the Midwives Acts, but he had no power to make a regulation providing that medical men to whom fees were due under this section might send their accounts to the local authority on the next occasion of sending out their accounts after attendance on the patients.

Dental Benefit

Answering Mr. Thomas Lewis, on July 23rd, Mr. GREENWOOD said that the total amount spent by approved societies on dental benefit from the commencement of the benefit to the end of the year 1930 was approximately £10,500,000. It was impossible to state what effect this had upon benefit funds, but its importance in reducing liability to ill-health was recognized.

Climate and Mosquitos.—Mr. GREENWOOD said, in reply to *Major Carver on July 16th, that he was advised that the* seasonal conditions of the present year, taken with those of last winter, had in general resulted in an unusual abundance of mosquitos of sylvan species. No specific information regarding the increase of other insects had been brought to his notice, nor any evidence of new or exceptional danger to health from insect prevalence.

A "Remedy" for Tuberculosis.—Mr. GREENWOOD told Mr. Smithers, on July 16th, that his attention had been directed to a treatment for tuberculosis called umckaloabo, but it had not been examined by his Department. Claims made in regard to this alleged form of treatment for tuberculosis did not appear to differ in character from those made for many other so-called "remedies" which had been advertised and afterwards found valueless. He did not consider there was sufficient ground for instituting a clinical investigation.

Foot-and-Mouth Disease.—On July 20th Dr. ADDISON told General Clifton Brown that, since June 17th, sixty-nine cases of foot-and-mouth disease had been confirmed in Great Britain. The animals treated with foot-and-mouth disease serum during the period were: 1,057 cattle, 2,089 sheep, and 56 pigs. Of these, one animal contracted the disease.

War Pensions.—In the House of Commons, on July 21st, Major COHEN asked leave to introduce a Bill to repeal Section 5 of the War Pensions Act, 1921. He said that at present large numbers of ex-service men were suffering from something which they genuinely believed to be due to war wounds, but, more than seven years having elapsed between their discharge from the Army and the time when their wounds or disease became manifest, they were debarred from making a claim or from going to an appeal court. The passage of the Bill would give a right of appeal in all claims. Leave was given to bring in the Bill.

Teeth of School Children.—Replying to Mr Harris, on July 23rd, Mr. LEES-SMITH said that during the year ended December 31st, 1930, 2,840,000 children in public elementary schools in England and Wales were inspected by school dentists. Of these, 1,975,000 were found to require treatment and 63.4 per cent. of this latter number received treatment under arrangements made by the local education authorities.

Nurses in Mental Hospitals.—Answering Sir N. Grattan-Doyle on July 23rd, Mr. GREENWOOD said the number of women nurses now employed in the nursing of male patients in public mental hospitals was approximately 320; they were mainly employed in the infirmary wards. The principle had been the subject of careful consideration by the central and local authorities for many years, and the practice of employing women in the nursing of selected male patients was of long standing. The Royal Commission on Lunacy, which reported in 1926, recommended more general employment of women nurses in certain male wards.

Superannuation of Asylum Officers.—In reply to Mr. Ramsbotham, on July 23rd, Mr. GREENWOOD said he could make no statement on the action which he intended to take in

consequence of the actuarial investigation into the superannuation of asylum officers The investigation was on the point of completion

Transfer of Poor Law Institutions —Mr GREENWOOD told Mr Somerville Hastings, on July 23rd, that appropriation of transferred Poor Law institutions for the purposes of the Public Health Acts had been effected by the London County Council and by the county borough councils of Birmingham, Bradford, Bristol, Cardiff, Coventry, Derby, Halifax, Leicester, Manchester, Middlesbrough, Newcastle on-Tyne, Oldham, Plymouth, Reading, Rochdale, Southend on-Sea, Sheffield, Southampton, Sunderland, Warrington, and West Bromwich Applications for consent to such appropriation were under consideration from the county councils of Glamorgan and the North Riding of Yorkshire, and from the county borough councils of Burnley and Preston.

Milk for School Children —Two education authorities in Scotland—West Lothian and Selkirk—have adopted schemes for the supply of milk to school children under the provisions of the Education (Scotland) Act, 1930

Notes in Brief

Replying to Mr Sorensen, on July 16th, Mr Greenwood stated that admission hospitals had been provided, or were under construction, at about a quarter of the public mental hospitals

The conveyance by road of dangerous substances, including vitriol, is receiving the attention of the Home Secretary

The Home Secretary has recently circulated for purposes of discussion draft regulations dealing with head lights on motors

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

NATIONAL UNIVERSITY OF IRELAND

At a meeting of the Senate on July 16th, the reports of the examiners on the results of the summer examinations, 1931, were considered, and passes, honours, etc , were awarded in connexion therewith.

The following appointment was made Lectureship in Clinical Pathology in University College, Cork, William J. O'Donovan, M B , B Ch , B Sc , D P H

The following representatives of the University were appointed to the 250th anniversary celebrations of the Royal College of Physicians of Edinburgh: Professor Henry F. Moore, M.D., D.Sc., Professor P. T. O'Sullivan, M.D., and Professor Thomas Walsh, M.A., M.D.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

A quarterly meeting of the Royal College of Physicians of Edinburgh was held on July 21st, with the President (Sir Norman Walker) in the chair.

Dr. George Hector Percival, Dr. David Lees, D.S.O., Miss Margaret Black Martin, and Dr. Joseph Ryland Whitaker, *M.C.*, all of Edinburgh, were introduced and took their seats as Fellows of the College.

Dr. Thomas Douglas Inch, O.B.E., *M.C.* (Gorebridge), Dr. Walter John May (Durban), Dr. Edward Robert Charles Walker (Aberdeen), and Dr. David Taylor Mackie (Exeter) were elected Fellows of the College.

Dr. James Collier, F.R.C.P.Lond., was appointed Morison Lecturer for 1932.

Kirk Duncanson Fellowship for Medical Research

In accordance with the bequest by Mrs. Isabella Kirk Duncanson to commemorate the late Dr. J. J. Kirk Duncanson, the Council of the Royal College of Physicians of Edinburgh will award the Kirk Duncanson Research Fellowship in October, 1931. The Fellowship will be awarded annually for a period of one year. It may be renewed to the same beneficiary for two additional periods of one year each. The emolument will be upwards of £150 for the first year, about £250 for the second year, and about £350 for the third year. In recognition of Dr. Kirk Duncanson's interest in diseases of the ear, nose, and throat, in making this first award special consideration will be given to the claims of candidates who propose to devote themselves to that branch of medicine. Applications and recommendations, with particulars of the special line of research contemplated, and of the place where the investigations are to be conducted, should be in the hands of the secretary of the College by October 15th, 1931.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH

At a meeting of the Royal College of Surgeons of Edinburgh held on July 23rd, Dr. James Haig Ferguson (President) in the chair, the following twenty-six successful candidates out of ninety-six entered, who passed the requisite examinations, were admitted Fellows.

G. G. Ambegaokar, D. W. Bawtree, A. J. Brown, J. R. J. Cameron, C. N. L. Cantor, H. Carter, J. J. Coulthard, D. S. Davies, J. B. Dewar, D. I. C. Finlayson, H. P. Forster, N. G. C. Gane, R. G. Hutchison, J. G. Kingsbury, L. E. Lane, J. C. Mavo, J. H. Otty, L. B. Patrick, R. G. Paul, T. M. Reid, E. M. Robertson, E. H. T. Rutherford, R. Sampson, W. N. Searle, B. C. Smeaton, D. Wardrop, Miss Rebecca E. Roulston.

The Ivison Macadam Memorial Prize, consisting of a bronze medal and a set of books, was, after a competitive examination in organic and inorganic chemistry, awarded to Miss Marjorie B. Morton, who was also awarded the Henry Arthur Dalziel Ferns Bursary.

Medical News

Lord Moynihan, President of the Royal College of Surgeons of England, sailed for South America on July 24th, to take part in the forthcoming medical conference at Buenos Ayres.

The Fellowship of Medicine and Post-Graduate Medical Association announces that, from August 4th, continuing through the month, a course in urology will be held at the All Saints' Hospital; fee, £2 12s. 6d. The Queen's Hospital for Children will undertake an all-day course from August 17th to 29th, instruction being entirely by demonstration of cases, medical as well as surgical; lunch and tea are provided by the hospital authorities; fee, £2 2s. The Brompton Hospital will hold a course from September 7th for one week, the Bethlem Royal Hospital from September 8th to October 3rd, the Infants Hospital from September 14th to 26th, the Central London Ophthalmic Hospital from September 14th to October 10th, the Westminster Hospital from September 14th to 26th, and the Metropolitan Hospital from September 28th to October 10th. Detailed syllabuses may be obtained from the Fellowship, 1, Wimpole Street, W.1. (Langham 4266).

The Medical Research Council announces the follow awards of Dorothy Temple Cross Fellowships for 1931- under the terms of the benefaction in that name research fellowships in tuberculosis: Charles Allan Bir M.D., M.R.C.P., senior medical registrar and tutor, Ro Infirmary, Liverpool; Roy Lars Vollum, M.A., D.Ph demonstrator in pathology, University of Oxford. Birch has received a Fellowship for the study of proble of tuberculosis at industrial centres in the United Sta Dr. Vollum will study recent developments in meth for the investigation of tuberculosis in Germany Austria. The Fellowship awarded last year to Lieuten S. M. Burrows, R.A.M.C., late clinical assistant, tuber losis department, St. Thomas's Hospital, has been renev for a further year.

For the second year in succession a group of Ameri medical men are about to pay a visit to the princi thermal stations of France. The party, led by Dr. Cha Gordon Heyd, president of the Medical Society of State of New York, are due at Havre on August 7th, will be given an official reception by French Governm authorities. In Paris they will be received at the Colo Exhibition by Marshal Lyautey, the General Commissio and four days will be spent at Vichy.

We are asked to announce that the out-patient dep ment of the National Hospital, Queen Square, will closed on all out-patient days during the first three we in August.

Lord Balfour of Burleigh has been elected President the Royal Sanitary Institute, in succession to the Duke of Northumberland.

The forty-second international post-graduate course the Vienna University Faculty of Medicine will be h from September 28th to October 10th, the subject be recent therapeutic advances in all branches of medic The fee for the course is 50 Austrian shillings, and furt information may be obtained from the secretary, Dr. Kronfeld, Porzellangasse 22, Vienna, IX.

An interesting microphone and loud-speaker installa has recently been carried out in the surgical clinic of University of Milan. The apparatus is intended for use of the professional staff when performing or direc operations, to describe the surgical manipulation to students who sit in a gallery surrounding the opera theatre, but separated by glass from it. The installa consists of a bar microphone, a 1½ W. mains ampli and a protos loud speaker.

The Kerckhoff Institute for the study of affections the heart, built from a donation of a million dollars Mrs. Louise E. Kerckhoff of Los Angeles as a memo to her husband, has been opened at Bad Nauheim. building, in classic style, consists of two main cut structures with a connecting wing. It contains auditorium seating 600 persons and intended for gresses, and a smaller lecture room. A medical libr and a museum with representations of methods of trea circulatory disturbances, physical diagnosis and ther balneological collections, etc., are at the disposal investigators. The institute will conduct special contin tion courses open also to foreign physicians. It is divi into five main departments: one for patients sent to Nauheim under the German social insurance system statistical department devoted to research into the ca of cardiac diseases; a department for educating the pu as to causes and treatment of such diseases; another their study and treatment; and a department cove treatment by physical methods, especially baths. Profe Groedel is at the head of the institute, for the ma tenance of which Mrs. Kerckhoff has provided a f of one million marks

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM* 9861, 9862, 9863, and 9864 (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology, Westcent, London*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate, Westcent, London*

MEDICAL SECRETARY, *Mediocra, Westcent, London*

QUERIES AND ANSWERS

Effect of Prolonged Injections of Insulin on Subcutaneous Tissue

"D M" writes: In the *Journal* of June 27th and July 4th are inquiries about loss of subcutaneous tissue resulting from insulin administration. This can be a very real trouble to a diabetic. I have under my care a lady who has required very heavy doses of insulin for nearly seven years, all four limbs being used for injections. For over five years no loss of tissue was observed, but for about eighteen months the thinning of the parts used for injection has been very striking. I should be glad to know from someone with wide experience of insulin treatment (1) any explanation why this should occur in exceptional cases, (2) whether the occurrence has any relation to large doses and prolonged administration.

Lochnera Rosea

Dr JOHN M DALZIEL writes from The Herbarium, Royal Botanic Gardens, Kew: I shall be grateful for any information with regard to the medicinal use of the "Madagascar periwinkle"—*Lochnera* (*Vinca*) *rosea*. The leaves are said to be a remedy for diabetes in South Africa, and a proprietary medicine called "covinca" is in use there. Is there any published record of investigation either of its properties or of its clinical value in that disease?

The Cigarette Habit

"BUNGALOW" would be glad of any "tips" to help a weak-minded patient to overcome excessive cigarette smoking.

A Cosmetic Query

Dr I G BRIGGS writes: I have a lady patient, aged 30, who uses the ordinary good class cosmetics for the face, but for some ten days before to five days after the menses suffers from a few pimples (which are negligible), and a condition in which the pores are very widely open, causing an unpleasant "greasy" feeling (no perspiration). The patient is a demonstrator for cosmetics, and in this condition, when powder is applied to the face as it has to be during her employment the enlarged pores show very noticeably, and are a hindrance. Can any reader suggest treatment? The patient has tried astringent lotions.

Tennis Blisters

"L E P" writes, in reply to "T W S" (Surrey): Blisters on the feet (and hands in tennis players) are generally due to free sweating. This can be arrested and the skin made hard and dry by painting with a saturated solution of picric acid in spirit, allowing it to evaporate, and then washing in many changes of water to prevent staining of bedclothes, etc. The drawback to this method is the ugly discoloration of the skin, and more particularly of the nails which—negligible in the case of the feet—is very noticeable in the case of the hands. However, it is *effective*.

Income Tax

Claim for Sundry Expenses

"B W" inquires whether he can deduct as professional expenses the cost of (1) advertising for an assistant (2) drawing up agreement in connexion with the assistant and (3) renewal or replacement of such books as the *Medical Directory*.

*** The answer is in the affirmative in each case, with one possible qualification. If the agreement with the intended assistant contemplates his becoming a partner, to that extent it deals with the constitution rather than the actual carrying on of the practice, and in such circumstances the claim to deduct the costs of his engagement would be incorrect, at least as regards a part of such costs.

Car Transactions

"F F S" sold a car in April, 1931, for £175 and bought another in replacement for £330. What can he claim?

*** He can claim the out-of-pocket expense of £330 - £175 = £155 as a professional cost of running the practice during the year 1931. If, however, the car sold cost less than £330, he can claim only the excess of the cost over the £175, the balance in such a case representing the cost of improving the car equipment.

LETTERS, NOTES, ETC.

The "Medical Directory"

Messrs J and A CHURCHILL, publishers of the *Medical Directory* (40, Gloucester Place, Portman Square, W.1) write: The annual circular has been posted to each member of the medical profession. If the form has not been received a duplicate will be sent on request. We shall be grateful for the return of the forms by an early post.

"The Hawker Nuisance"

Dr E H. STRANGE (London, E.5) writes: Owing, no doubt, to the prevailing trade depression the hawker of doubtful preparations and appliances seems this year a more than usually frequent visitor to one's consulting room. The technique is in all cases the same. An individual of immense self-assurance at once lets forth a flood of patter as to the merits of a preparation, it may be, to keep one's professional plate and car bright and untarnished for several months, or of a device to sterilize instruments in a tumbler or a jug in two minutes. He claims to be the inventor of the preparation or appliance, and claims that it is new. He shows one by the counterfoils in his order book that many of one's neighbours and friends have fallen for his patter. He makes great play with the fact that he is not taking money at once, one pays C.O.D. later. But the medical man is never allowed to test a sample or examine the appliance at leisure. Goods thus hawked around are trash at the price demanded. The guinea appliance was not invented by the hawker, neither is it new. It can be bought from any electrical firm for about a quarter the price the hawker asks. The preparation with the fancy name for which he asks 15s. 6d. for four ounces is an old one, which can be bought at a few shillings a pint. It would be a service to many a busy practitioner if medical men would tell every hawker, including the hawker of medical books, at once two simple and obvious truths: (1) firms of repute do not hawk their goods around (2) goods which are hawked around are made to be hawked around, and would not be saleable by any other means than high power salesmanship and bluff. The price demanded is far above the market value.

Corrigendum

Our account of the presentation to Dr Arnold Lyndon (July 11th, p. 72) contained a slip which should be corrected. Dr Lyndon was chairman of the Surrey Panel Committee from 1920 to 1931, a period of eleven years. His predecessor in the chairmanship (1913 to 1920) was Dr Cecil Lankester of Guildford.

Vacancies

Notifications of offices vacant in universities, medical colleges and of vacant resident and other appointments at hospitals, will be found at pages 43, 44, 45, 46, 47, 50, and 51 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 48 and 49.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page *120*.

BABY'S ONLY FOOD FROM BIRTH TO 2½ YEARS

ROSARIO
18th May, 1931

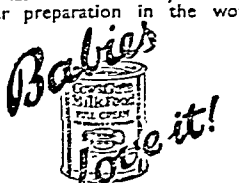
To Messrs. Cow & Gate, Ltd.
Guildford, ENGLAND

Dear Sirs,

Until two months ago Baby has been existing only on Cow & Gate milk, as she refused to take any solid food. Everyone told me she *ought* to be eating other food, but *evidently* what she *did have* made up for it, and everyone remarked how bonny she was and what strong bones and muscles she had. We would not be without it for worlds and thoroughly recommend it to all our friends.

She still has three breakfast-cups a day—one on getting up in the morning, one at siesta time and one on going to bed—and thoroughly enjoys it and has never had one minute's discomfort, even during our extremely hot summer days. She is very intelligent and bright.

I remain, Yours very truly Hilda J. Taylor.



Name:
ESME HILDA TAYLOR

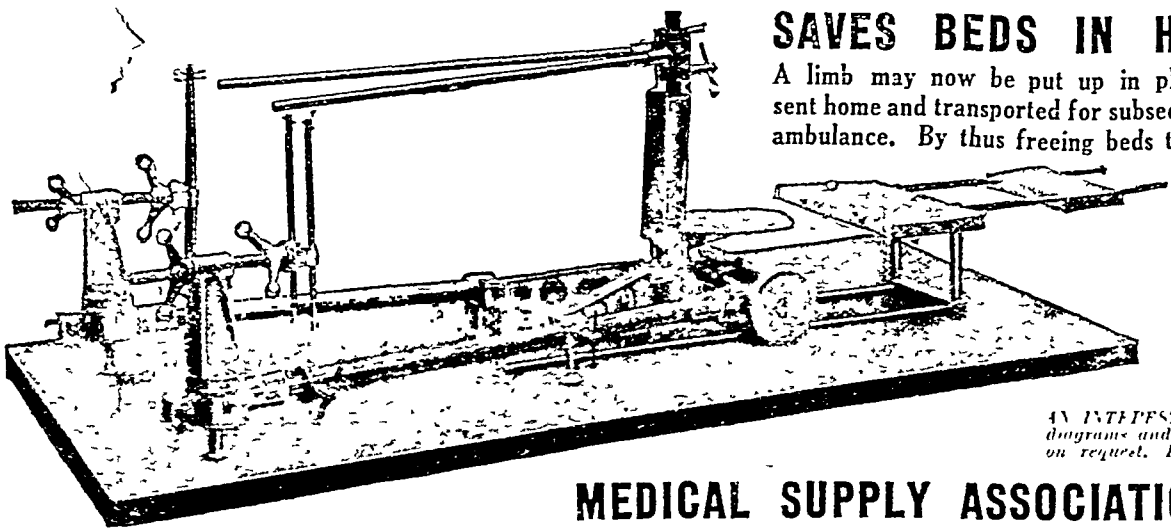
ORTHOPAEDIC BANDAGES



An IMPROVED and MODIFIED

Portable Traction Apparatus

An exceedingly efficient and convenient apparatus for putting up in plaster the lower limbs or trunk; also when applying bone plates or Parham and Martin's Bands to long bones of the lower extremity. Provides the more essential movements of expensive and bulky Orthopaedic tables at a fraction of the cost.

Quickly adaptable for the following positions:

Extension of whole lower limbs.
Movements about hip-joint:
Abduction to any degree—
Hyperextension—Flexion—
Internal and External Rotation.
Flexion of knee-joint.
Inversion and Eversion of foot.

SAVES BEDS IN HOSPITALS

A limb may now be put up in plaster, the patient sent home and transported for subsequent treatment by ambulance. By thus freeing beds this new apparatus saves its cost many times over.

Folds compactly for storage or transit in plywood case 35 in. × 15 in. × 11 in.

AN INTERESTING LEAFLET giving diagrams and instructions for its use on request. Please ask for a copy.

"VARIBAN"

Elastic Plaster BANDAGE

MADE from a specially woven selvedge material, possessing very elastic properties, evenly spread with an Antiseptic Zinc Oxide Paste. Self-adhesive, readily conforming to the shape of the limb, and when carefully applied forms an even surface dressing which will not crease or slip. Firm support. Easy to remove. Extensively used in many well-known hospitals for the treatment of VARICOSE ULCERS, VARICOSE VEINS, SURGICAL and ORTHOPAEDIC CASES, etc. Their application for treatment of Varicose Ulcers, etc., does not necessitate the patient lying-up; in fact, permits the continuance of light duties. Ensures rapid healing.

SUPPLIED in WIDTHS

DEAF DOCTORS

AND DEAF PATIENTS

have proved "ARDENTE" a boon—a Heart Specialist whose work is so dependent on his hearing writes: *"'Ardente' is a godsend to me";* without "ARDENTE" he is, to all intents and purposes, "stone" deaf; with "ARDENTE" he carries on his work—what better testimony to "ARDENTE" merit?

Mr Pent makes a Stethoscope specially for deaf Doctors—the only one of its kind, which is widely used and praised Doctors whose work lies amongst the deaf prefer to prescribe "ARDENTE" because they know that "ARDENTE" is the only individual method in the whole deaf world (no mass production way can ever succeed with human disabilities) and they know what "ARDENTE" service stands for to the deaf Many doctors who are deaf use ARDENTE

"ARDENTE" is entirely different and unequalled and succeeds in widely differing cases A full range covers the needs of those suffering from varying forms and degrees of deafness and tinnitus Minutely adjusted to the requirements of the case for young, middle-aged, or old, and so sensitive as to have the desired effect even in middle ear and nerve cases, bringing into action and stimulating the auditory system, enabling it to function naturally and easing atrophy ARDENTE can be used or not at will and is sold under guarantee

"ARDENTE" is the choice of Doctor and patient—only after test and hearing or from prescription or particulars is "ARDENTE" fitted tested, tried adjusted, supplied, and serviced

RELIEVES CONSTIPATION

Test Sal Hepatica for yourself and you will agree that it is by far the most satisfactory laxative yet developed. There is no pleasanter or more effective way of eliminating from the system harmful toxic amino acids. The presence of such evils in the system gives rise to rheumatism, lumbago, neuritis and many other maladies that have their source in auto-intoxication. Remember too that Sal Hepatica is essentially non-habit-forming. It's daily administration leads to a "time habit" which is invaluable in combating chronic constipation.

Sal Hepatica contains sodium sulphate, sodium phosphate, sodium chloride and lithia citrate in an effervescent medium.

Samples for clinical trial will be forwarded on request to duly qualified members of the medical profession on application to Bristol Myers Company, 112, Cheapside, London, E.C 2.

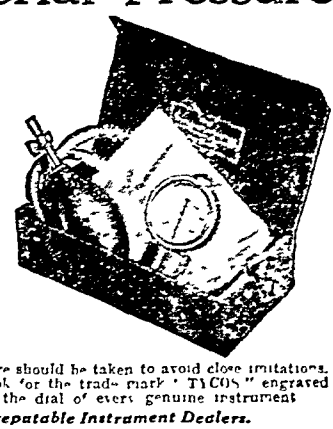
Is it fair to your best friend to make him your Executor? The duties are onerous, and usually thankless; the responsibilities are great and the penalties for neglect are severe. Moreover, he may die, and the expense of appointing his successor is considerable. On the other hand, if you appoint the Westminster Bank instead, the fees (which are paid out of your estate) will probably be only a fraction of the legacy which you would have left to a private trustee.



Ask for the 'Executor and Trustee' booklet at any local branch, or call at

WESTMINSTER BANK

LIMITED

Accurate Arterial Pressure Readings

For visiting purposes the TYCOS Portable Sphygmomanometer amply fulfils the Physician's needs Although one of the most delicate and accurate instruments of the medical man's equipment, the portable type as illustrated can be carried without fear of breakage There is no glass tubing to break, no mercury to spill, and the readings can be verified at a glance by comparing the relation of the hand to the immovable zero

Care should be taken to avoid close imitations. Look for the trade mark "TYCOS" engraved on the dial of every genuine instrument

Obtainable from all reputable Instrument Dealers.

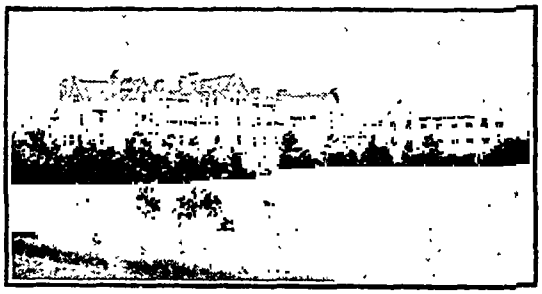
"The Rose Corset-Belt"

for Accurate Abdominal Support and Comfort



Extract from the "British Medical Journal," Dec. 10th, 1927—

"Visceroptosis is the cause of so much discomfort and ill health and an ill-fitting or wrongly applied belt or corset may aggravate rather than diminish the subjective effects of this condition . Madame Rose has for many years devoted special attention to this problem, and we have good reason to believe that she has given help and comfort to a considerable number of sufferers We have received assurances from medical men, who have sent patients to her, that she gives personal attention to each patient, that she takes great care in adapting and adjusting the support to the particular needs of the case "

BETHLEM ROYAL HOSPITAL, for Nervous and Mental Disorders,

Monks Orchard, Monks Orchard Road, Eden Park, Beckenham, Kent.

Reg. Tel. Address: Bethlem, Beckenham. *Telephone*: Springpark 1180—1181.

Station: Eden Park (Southern Railway).

President: LORD WAKEFIELD OF HYTHE, C.B.E., LL.D.
Treasurer: SIR LIONEL FAUDEL-PHILLIPS, Bart.
Physician-Supt.: J. G. PORTER-PHILLIPS, M.D., F.R.C.P.

This Registered Hospital is now situated at Monks Orchard, in some 250 acres of park, pleasure, and farm grounds.
Applications can be considered on behalf of patients of the educated classes in a presumably curable condition.
With a view to early treatment voluntary or uncertified patients are admitted.
Patients who can contribute 5 guineas weekly towards the cost of treatment and maintenance may be received as vacancies arise.
The Committee will also consider applications for admission at lower rates, and in certain cases will be prepared to admit patients free of charge.
Every facility for specialized investigation and treatment is provided in the Lord Wakefield Science and Treatment Unit. In this Unit is found the X-ray and Dental Departments and the Bio-Chemical, Pathological, and Psychological Laboratories.
Furthermore, provision is made for Electro-Therapy and Hydro-Therapy to be carried out in all their forms.
In addition to the Resident Medical Staff, Consultants in special branches of Medicine and Surgery are available whenever required.
The comfort of sensitive patients is greatly enhanced by the fact that the majority are given single bedrooms.
For forms and further particulars apply to the Physician-Superintendent at the Hospital.

THE OLD MANOR SALISBURY

A Private Hospital for the Care and Treatment of those of both sexes suffering from MENTAL DISORDERS.

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS.

NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

Trustee: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. ROBERTS, M.A., M.D.

This Registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or who wish to prevent recurrent attacks of mental trouble, temporary patients, and certified patients of both sexes are received for treatment. Care in clinical, biochemical, bacteriological and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods including Turkish and Russian baths, the prolonged immersion bath, Vichy douche, Scotch douche, Electrical bath, Pyrethurex treatment, etc. There is an Operating Theatre, a Dental Surgery, a X-ray Room, an Electrical Apparatus and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for bacteriological, biochemical, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Patients may visit this branch for a short period, change of air being of great importance. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56 Northampton) who can be seen in London by appointment.

HAYDOCK LODGE,

NEWTON-LE-WILLOWS, LANCASHIRE.

Time: 11 miles from Manchester.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES either voluntarily or under Certificate. Patients are classified in separate buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self-supported by its own farm and gardens, in which patients are encouraged to occupy themselves. Every facility for indoor and outdoor recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT.

All communications to be addressed to Mr. A. V. STOREY, General Manager.

Before the Operation and After

In preparation for the operation  one tablespoonful of Agarol on retiring  in place of the usual castor oil, will insure against gastric upset.  Again, a few days later  when the patient begins to take nourishment  Agarol in half doses  is the logical eliminant because it stimulates peristalsis  gently without griping or pain.

AGAROL Brand Compound is the original mineral oil and agar-agar emulsion with phenolphthalein. It softens the intestinal contents and gently stimulates peristalsis.

Agarol Brand Compound is palatable without artificial flavouring and easy to take. The usual dose in chronic constipation is a tablespoonful, reduced as improvement takes place.

A supply gladly sent for trial.

AGAROL *for Constipation*

Patent No 253 527.

BRITISH MADE

ELASTOPLAST BANDAGES are not only the proved cure for Varicose Ulcer, but are ideal for all Surgical and Orthopaedic work. They provide perfect support and compression for the after-treatment of Fractures, for Sprains, Strains, Dislocations, Varicose Veins, &c.

ELASTOPLAST DRESSINGS are the last word in Scientific First Aid. They combine medicated gauze and lint pads, with the Elastoplast base.

VISCOPASTE BANDAGES
(Unna Paste type)
are a valuable adjunct to the after-treatment of Varicose Ulcers, &c.

ELASTOPLAST will reduce your dressings accounts, save your time, increase the efficiency of the injured person, and moreover ensure cleanliness.

Literature and cuttings will be sent on application, or a trial set containing full Bandages and a range of Dressings upon receipt of P.O. value 2 6 (Overseas postage extra) by the manufacturers:

Issue of the BRITISH MEDICAL JOURNAL is this week 39,000 copies.

THE
EXTRA PHARMACOPOEIA
By W. HARRISON MARTINDALE, Ph.D.

Nineteenth Edition.

Vol. I, 27/6 net; postage 6d.
Vol. II, 22/6 net; postage 4d.
Complete Work (2 Volumes) 50/- net, post free.

In Two Volumes.

Vol. I (1928) deals chiefly with Treatment, giving the important issues as to CLINICAL USE of all modern CHEMICALS and DRUGS, characters, dosage, methods of prescribing, etc.
Vol. II (1929) COMPLETES THE SET. It is concerned with INVESTIGATIONS, EXPERIMENTAL RESEARCH, DIAGNOSIS, and a large amount of new matter in medicine and allied sciences.

BRIT. MED. JOURN., Nov. 2nd, 1929, says: "*Has a well established reputation as a most useful and convenient work of reference.*"
LANCET, Nov. 2nd, 1929, says: "*A clear and authoritative publication of the highest value.*"

Up-to-date Book for everything on the Therapeutic Use of Drugs. It embodies the Latest and Most Varied Information on Chemistry, Pharmacy, Therapy, and numerous other subjects.

AND THE MOST EFFICIENT SUPPORT ON THE MARKET!

The Curtis Abdominal Support Model No. 1 Skeleton type is lighter and more hygienic than any other support on the market, whilst its efficiency is in no way impaired. The average weight for a person with a hip circumference of 32" is only 10 ozs. All covering is detachable and washable, and each appliance is supplied with a spare set of covers at an inclusive charge of £3 : 12 : 0.

FOR DEAFNESS

Doctors prefer "ARDENTE" because—

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises, giving inconspicuous hearing.
4. It conveys sounds from varying ranges and angles.
5. It is entirely different, uncopiable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf through various causes.
7. It is helpful for conversation, music, talkies, wireless, home, office, public work, and sports.

FREE HOME TESTS

arranged for Doctors and Patients.

Medical Prescriptions made up to the minutest detail.

"ARDENTE" STETHOSCOPE.

Mr. R. H. Dent makes a Stethoscope especially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, as evidenced by the interest shown at the last B.M.A. Meeting

MEDICAL REPORTS

Commended by all leading medical journals.—Mr. Dent will be happy to send full particulars and reprints on request.

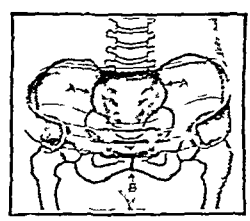
Kodak Limited (Medical Dept.)
Kodak House, Kingsway
London, W.C.2



For the Relief of Sacro-iliac Relaxation or Strain.

WHEN a sacro-iliac lesion has been caused by heavy lifting, child-birth, bad posture, or other conditions, a Spencer Belt relieves the condition by immobilizing the articulations involved.

Fixation of the sacro-iliac joints is achieved by means of a Spencer specially designed belt or corset whose inner band, fitted with a pad, acts as a fulcrum in securing proper adjustment.

The sacro-iliac band which is built inside the corset or belt can be adjusted as tightly as necessary from the outside after the belt or corset is in place. Since the band is built into the Spencer Support, it never rides out of position. It holds the bony structure in position, thus relieving tension or pressure and hastening the return to normal condition. Each Spencer Support is specially designed for the patient who is to wear it. The Spencer Corsetière in your own town will call at your Surgery or at your patient's home to take measurements under your supervision. Spencer Supports and Corsets are never sold in shops.

The shadowgraph above shows the position in which the special inner belt is applied to the body. This is not a complete garment worn by itself, but a part of a Spencer Sacro-iliac Corset or Belt which holds it in position.

Strontii Bromidi	5 gr.	Tinct. Adonis Vernalis	5 m.
Tinct. Valer. Deodorat.	10 m.	Tinct. Visci Alb.	5 m.

Useful for functional nervous affections, particularly in controlling epileptic seizures.

Price 5/- lb.

FULL LISTS ON APPLICATION

Evans'

PURGOIDS

Purgoids present a most effective combination of Phenolphthalein, Aloin, Ipecacuanha, Belladonna, etc., in sugar-coated tablet form. They are of great value in cases of constipation, peristalsis being promoted without griping, and intestinal secretion increased.

In addition to their use in constipation of long standing, Purgoids are to be commended as a general aperient in temporary conditions and after operations.

THE

DOCTOR'S CHINA TEA

WHY IT IS PRESCRIBED FOR GASTRIC PATIENTS.

When ordinary tea is out of the question it is essential that only really good China should be drunk. The Doctor's China Tea has won the enthusiastic approval of practitioners simply because it is a perfect blend of a good China leaf with all excess tannin eliminated. It can therefore be prescribed for invalids and dyspeptics with safety—it has no ill after-effects.

TABLETS "B.S.C."

TRADE MARK

(Bile Salt Compound)

For Constipation, Intestinal Toxæmia, Hepatic Deficiency, Gall Stones and allied conditions.

Tablets "B.S.C." contain active pancreatic extract and bile acids, extract of duodenal mucous membrane and a proportion of ipecacuanha and emodin. Their administration stimulates the flow of glandular secretions which complete the digestive processes; the bile salts emulsify and detoxicate the food residue, while the emodin and ipecacuanha exert a tonic effect on the visceral musculature, particularly the colon, thus stimulating peristalsis.

Tablets "B. S. C." are of particular value in the treatment of constipation, hepatic disorders and the toxæmias arising from stasis. In conjunction with hexamine, they are of distinct benefit in the treatment of gall-stones and cholecystitis.

Supplied in bottles containing 40, 80, 160 and 500 at 2/6, 4/6, 8/6 and 20/-

BUST OF HOMER

Intestinal Atony

For establishing a natural daily evacuation of the bowels "Cristolax" offers a desirable form of treatment in every respect. It is not habit-forming and obviates the need of purgatives, which often produce harmful results.

Under the use of "Cristolax" tone is given to the digestive process, inspissation of the faeces prevented and a healthy condition of the bowel maintained. Further, no leakage of oil occurs from the rectum, as usually happens when liquid or semi-liquid forms of paraffin are used.

Briefly described, "Cristolax" is a digestant, lubricant, and bowel eliminant. It is in the form of fine granular crystals, presenting an attractive appearance. The taste is so very palatable that the product has been described as being "as nice as sugar-candy."

When children lack Vitamin "B"

Partial deficiency of vitamin B may be suspected in children when strength, growth and resistance to disease are impaired and there is evidence of gastro-intestinal disturbance. The encouraging results attending the use of Bemax in such cases suggests that this rich source of natural vitamins should be a regular part of the daily diet of every growing child.

Bemax is a preparation of the detoxicated embryo of cereals, very rich in natural vitamin B, and containing vitamins A and E. It is a pleasant food, welcomed by children for its flavour. Taken regularly it stimulates healthy growth, promotes digestion, checks *constipation and tones the system* to vigorous health and resistance to disease. In convalescence its tonic properties are invaluable.

Laboratory Reports on Bemax and Clinical Sample for personal trial will be sent to any Medical Man on request.

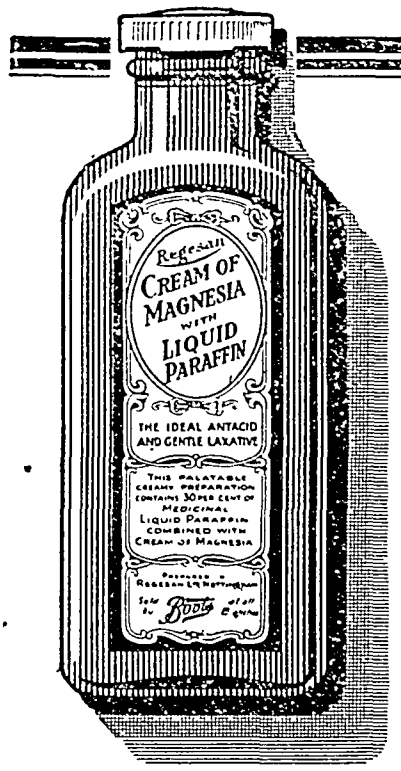
HORLICK'S

DURING THE HALF CENTURY of its existence, Horlick's Malted Milk has gained for itself a high place in the esteem of the Dental Profession. Composed of pure, full-cream cow's milk and the soluble extracts of malted barley and wheat, Horlick's is a complete and balanced food, and if necessary can well be made the sole item of diet. It forms a food-drink of cream-like consistency, which admits of adequate nourishment being taken at a time when ordinary foods are contra-indicated, either from absence of dentures or because of morbid conditions of the mouth, teeth or gums. At the same time, it gives rest to inflamed or injured structures in the buccal cavity. It is sound advice to recommend the taking of Horlick's both before and after any dental operation. Because of its valuable malt sugars it is a tonic and a stimulant, and, after anaesthesia, it assists in preventing vomiting. Horlick's promotes and maintains general fitness.

Valentine's Meat-Juice



FOR Quieting the Irritable Stomach and Aiding the Tired Digestive Organs, for Refreshing the Fever Patient and for Restoring and Strengthening when Other Food Fails, Valentine's Meat-Juice is used in Hospitals and prescribed by many leading Physicians and Surgeons.

Physicians are invited to send for Clinical Reports from Hospitals and General Practitioners in all parts of the world.

For sale by European and American Chemists and Druggists.

Valentine's Meat-Juice Co., Richmond, Vir., U.S.A.

Per 1/6 bottle

(Special discount to medical profession).

Regesan

CREAM of MAGNESIA with LIQUID PARAFFIN

(CONTAINS 30% LIQUID PARAFFIN)

A STABLE well-balanced combination containing 30% Liquid Paraffin held in suspension in a finely divided state. Its consistency is such that the tendency to leak exhibited by Liquid Paraffin is eliminated. Regesan Cream of Magnesia with Liquid Paraffin provides suitable treatment for all digestive troubles with which constipation and hæmorrhoids are associated. It is certainly the ideal laxative during pregnancy and lactation, and is suitable for infants and children.

Local Anaesthesia in Surgical Practice

REMOVAL OF CARBUNCLE.

Typical Case.

P. C., aged 45 years, physician (object strenuously to taking General Anaesthesia).

Diagnosis: Carbuncle of neck.

Operation: Excision.

Anaesthesia: Infiltration block using 60 c.c. of 0.5 of 1 per cent. Novocain-Adrenaline solution.

Operation: The infiltrating needle was carried 5 cm. beyond the outer edge of the carbuncle until the latter had been completely isolated from its nerve supply, when it was removed, absolutely without pain to the patient. The base was then cauterized and packed. The wound healed kindly.—EXTRACT from PRACTICAL LOCAL ANAESTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anaesthesia will be found in the above work, published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANAESTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify "Novocain" for your next operation.

Does not contain Cocaine, and does not come under the Dangerous Drugs Act.

PART OF A PAGE FROM A CAROLINGIAN MS. CONTAINING THE LEX ROMANA VISIGOTHORUM SALICA ET ALAMANNORUM.—Charlemagne found it necessary to frame a code of laws for his whole empire and to provide a copy for every judge. The examination of existing manuscripts confirms a valuable contemporary statement on this subject: "When Charlemagne had taken the imperial title, he noticed many defects in the legal systems of his people; for the Franks have two legal systems, differing in many points very widely from each other, and he therefore determined to add what was lacking, to reconcile the differences, and to amend anything that was wrong or wrongly expressed. He completed nothing of all his designs .... But he gave orders that the laws and rules of all nations comprised within his dominions which were not already written out should be collected and committed to writing." This scheme was not completed, nevertheless Charlemagne brought about many reforms.

DATE: A.D. c. 793—the MS. written.

A New Departure in Cigarette Manufacture

du Maurier

VIRGINIA

with the exclusive filter-tip

The Ministry of Health (Memorandum to Local Authorities, 8th Series). "No evidence has been adduced to support the contention that the mere inhalation and exhalation of tobacco smoke is of importance, although two possible causes of 'irritation' are *heat* and the *products of combustion.*"

The Claims of the Manufacturer

I. The filter-tip is selective in its action and while permitting the full passage of all the desirable constituents, shows a high capacity for retaining both the pyridine bases and non-volatile bodies, which undoubtedly form the principal source of throat irritation.

II. Unfiltered smoke is as dangerous as unfiltered water and as irritating as dust-laden air. The filter-tip effectively purifies tobacco smoke from harmful irritant and acrid substances which are inevitably formed when tobacco leaf, even of the finest quality, is burned.

III. By the introduction of the filter-tip the palate loses nothing, but the voice and throat gain immeasurably as the irritants are held in check without impairing the flavour or delicate character of the smoke. This is the central advantage to be gained from the filter-tip

IV. Cigarettes containing this filter-tip will be welcomed both by the medical profession and the public as a valuable means of preventing "smoker's cough" and other adverse effects on the pharynx, larynx or general health, traceable either directly or indirectly to the irritants and acrids in tobacco smoke.

V. They constitute the only safe form of smoking for those predisposed to, or suffering from, pharyngitis, laryngitis, or any form of bronchial or respiratory affection. They are invaluable in cases of gastric trouble due to tobacco tar.

A Selection from many Authoritative Endorsements

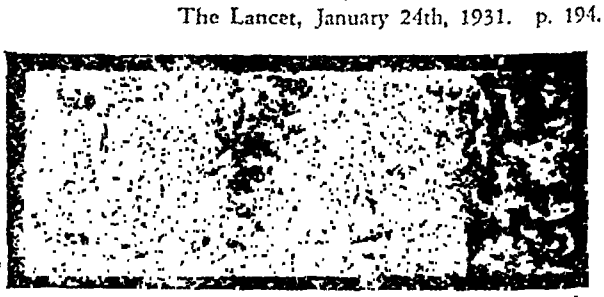
The aim of *this ingenious filter* is to trap the irritating pyridine derivatives and other non-volatile bodies, while permitting free passage of the agreeable volatile constituents of tobacco smoke.

The British Medical Journal, April 18th, 1931. p. 692.

A filter-tip must not only be efficient as a filter to irritating and noxious products, but must not affect the flavour . . . pyridine, the most offensive constituent of tobacco smoke, and other non-volatile irritant substances are retained by the ingenious filter-tip which is used in du Maurier cigarettes. From a personal trial we can testify to the *pleasant flavour and aroma* and to the *distinct lack of irritation* experienced in smoking these cigarettes.

The Practitioner, May, 1931. p. 584.

We have tested these cigarettes and find them to be *cooler* and *less irritating* to the mucous membrane than ordinary cigarettes of good quality without the filter-tip.



The filter-tip . . . retains bodies which are generally held to be the principal cause of throat irritation. Additional advantages of the filter-tip comprise *protection of the lips, teeth and fingers from unsightly stain,* and prevention of fragments of tobacco from getting into the mouth.

The du Maurier cigarettes may be regarded in every way as satisfactory, and they constitute a distinct and hygienic advance in the marketing of cigarettes.

The Lancet, January 24th, 1931. p. 194.

Cellulose fibre (contained in the filter-tip). BEFORE SMOKING.

Magnified view of cellulose fibre (contained in the filter-tip). AFTER SMOKING.

du Maurier Cigarettes at 20 for 1/-, 50 for 2/6, can be obtained from Peter Jackson, 217, Piccadilly, London, W.1, but we would prefer you to buy them from your tobacconist.

Peter Jackson (Tobacco Manufacturer) Ltd.

Observations

ON THE

FACTORS DETERMINING THE DIFFERENCE BETWEEN AN EPIDEMIC OF ONE DISEASE AND THAT OF ANOTHER*

BY

M. GREENWOOD, D.Sc., F.R.C.P., F.R.S.
PROFESSOR OF EPIDEMIOLOGY AND VITAL STATISTICS, UNIVERSITY OF LONDON

A critical examination of the title alone of this discussion is enough to show how hard a task we shall have to be precise. We should all find it difficult to devise a better title and yet it is almost as naïve as the question of a child to its elders. What *is* a disease? What are we to understand by the term epidemic? In the record of infectious diseases which is prepared in the division of epidemiology of the London School of Hygiene and rendered weekly to the Medical Intelligence Division of the Ministry of Health, one item is enteric fever. Week by week we compare the recorded incidence with what we call the expected incidence—namely, an average based on the experience of 1922-30. In this work no distinction is attempted between typhoidal and paratyphoidal infections because, from the administrative point of view and the etiological point of view of an epidemiologist, whose unit of observation is a group, not an individual, these biologically distinct infections lead to the same result. For the purpose in view they lead to but one disease, as we say. But, from the standpoint of prophylactic immunization, to bring together typhoidal and paratyphoidal infections would be ridiculous; from *that* point of view, they are two diseases. With still greater boldness, and the same practical justification, we do not distinguish between the influenzas of different years, although, in many respects, these are as different as phenomena can well be. In fact, we cannot provide a criterion of difference, or sameness, which will be satisfactory to all users of the term "disease." Similarly we cannot define epidemic adequately, any more than the victim of the sophist could tell when a heap of stones from which one stone at a time was subtracted, ceased to be a heap of stones. Yet, when this is said, we all feel that dialectical difficulties should not be allowed to frighten us from discussing a question which has interested members of our profession for thousands of years.

HISTORICAL AND STATISTICAL METHODS OF STUDY

The epidemiology of classical and Hellenistic Greek science was logical and self-consistent. According to Galen, there were three factors—two innate or acquired aptitudes of the body, the temperamental and procatarctic; and one external, the atmospheric katastasis. This latter determined the quality, and the two former the severity, of an epidemic.

> "So often as the katastasis of the atmosphere departs from its proper nature into the hot and humid, pestilential diseases must needs arise, yet will those chiefly be affected who were beforehand saturated with excrementous moisture while those who labour moderately and are temperate in diet remain refractory to such diseases." (*De Febrium Differentiis*, I.)

Translating from an obsolete notation into one more congenial to our habits of thought, Galen's view is that it is rather the condition of those exposed to infection than the nature of the infection which determines the difference, in the sense of our title, between one epidemic and another. He would explain the difference between the influenza of 1918-19 and that of 1931, not in terms of the katastasis, or, as *we* should say, specific differences of the infecting agent, but in terms of contrasting resistances.

Sydenham, on the other hand, enormously extended the sphere of the katastasis. He freed it from the naïve implications of such terms as hot, cold, moist, and dry, in modern speech, and popularized, if he did not actually invent, the doctrine of the epidemic constitution. He would have held that the influenza of 1918-19 differed from that of 1931 *essentially*, just as the port vintage of 1887 differed essentially from the vintage of 1897, because the complex of essential biological and cosmic factors had changed.

To some this will seem no more than archaeological triviality. What in the world have we, in the year of grace 1931, to do with Galen and Sydenham? The answer is that we are still wrangling about *their* problems, changing nothing but the notation. Some hold that the proper way to find out the truth is to do what Sydenham advised—to go back to Hippocrates's method and write the history of the epidemic constitutions not of Thasos but of the civilized world. Those who give this advice certainly resemble Sydenham in one respect, namely, in despising contemporary methods of research. They have no more use than Sydenham himself for statistical methods of study, except in so far as these methods can be directed against the abhorred bacteriologist. They say, quite rightly, that the statistical method is limited and selective; that it selects some only of the possible objects of study and these, perhaps, not the most important. I respect the ideals of epidemiologists of this class: I share their enthusiasm for medical history: I agree that there are many more things in heaven and earth than are recorded in the annual reports of the Registrar-General, or are amenable to the calculus of correlation. I can even bring myself to believe that Ballonius, Sydenham, or some wise man whose works I have not read, did really possess the key to all the mythologies of epidemics. But although we owe to students of history valuable criticisms, their creations have been less valuable. Perhaps Ixion was not the last person who mistook a cloud for the queen of heaven and engendered a race of centaurs.

On the other hand, the laboratory bacteriologist falls into the opposed error of over-simplification. His little world of individual experimentation is a very imperfect model of the world of men and women, and the inferences from the former extended to the latter have often made him fair game of the epidemiologists who have studied "real" epidemics.

In my view, a *via media* between the over-elaboration of the disciples of Sydenham and the over-simplification of the academic bacteriologists must be chosen. We must, by a deliberate limitation of the field of observation, try to discover which of the vast number of possibly influential factors are likely to repay study in the world of "real" epidemics. Within that limited field we must use the methods of statistical description which, although they have not enabled us to solve the problems of epidemicity, have at least been valuable instruments of sanitary administration. That is the case for experimental epidemiology.

The Section will, I think, be more interested in the bacteriological and immunological aspects of work in this field than in its purely statistical features. I shall therefore merely summarize what I believe to be probable epidemiological conclusions before making way for those more competent to deal with other sides of the work.

* Made in opening a discussion in the Section of Pathology and Bacteriology at the Annual Meeting of the British Medical Association, Eastbourne, 1931.

Scope of Experimental Epidemiology

Experimental epidemiology is an attempt to simplify the study of general epidemiology by (1) limiting the number of variable factors (for example, by rigorously excluding from the herd under observation all but one extraneous infection); (2) taking as the object of study a herd of short-lived animals, so that the time-scale of observations is magnified. These advantages are purchased, of course, at a heavy price. We can undoubtedly control many of the conditions of life of a herd of mice; but, on the other hand, our knowledge of the social biology of mice is more scanty than our knowledge of the social biology of men, and the conditions of life we can secure for our herds are no doubt very different from those appertaining to a colony of mice living, not in Gower Street, but in the sylvan world of mice. The application of our results to the elucidation of the problems of human epidemiology is therefore analogical at two removes. There is a gap between our mice and mice in general and a still wider gap between mice in general and men in general. We are, however, no rasher in this way than other experimental biologists are forced to be.

Outline of Investigation

A large majority of our studies have been of herds deliberately exposed to infection by either *Past. muriseptica* or *Bact. aertrycke*. Experimental herds have been assembled by bringing together naturally infected animals (survivors of previously infected herds) and healthy animals or inoculated and healthy animals. The herd so formed has been recruited either from healthy animals, healthiness being guaranteed by an extremely rigid process of quarantine, or from animals which have fulfilled other specified conditions. The results observed have been summarized or described in various ways. For the main purposes of this discussion, I shall use two. (1) The daily death rate at ages, which is precisely equivalent to the death rate at ages of our human vital statistics, save that age, in our studies, is cage age; entrance to the herd is, for our purposes, birth. (2) The expectation of life limited to the next sixty days. In human vital statistics, the expectation of life at any age, say 10 years, limited to any period, say 60 years, is the average number of years of life lived by persons aged 10 during the next sixty years of existence. All those who survive to 70 will be credited with sixty years each, all those who die between 10 and 70 will be credited with the number of years they survived. For mice, which live, perhaps, a thirtieth of the normal span of human existence (much less in infected herds) sixty days from entrance reduces the population of contemporary entrants to 10 per cent., or less, of its original strength, so that this measure, although subject to the objection which can be urged against *all* concise statistical measures, namely, that it ignores important details, is a comprehensive one. It is better than the complete expectation of life, that is, the average survivorship to the end of life, because this may be greatly influenced by the fates of a small number of exceptionally hardy individuals.

Secular Features of Herds

Before taking up the points to which I wish specially to direct your attention, I shall say a word on the ordinary secular features of the herds. Our experience is that the secular mortality of a herd undergoes vicissitudes graphically similar to what is seen in the mortality statistics of a community observed over several generations. [illegible] no more successful than have students of [illegible] in discovering a real "law" of periodicity [illegible] of the students of experimental epidemiology in other countries, we have not been able to satisfy ourselves that either seasonal variations or modifications of the diet determine the epidemiological history of the herd, under the conditions existing in our experimental series. We have, however, [illegible] once a herd has been infected with *morbi*, the resultant disease will [illegible] the herd for many generations, emerging [illegible] quiescence which, in terms of human [illegible] be very long, provided the herd be regularly [illegible] *healthy*, non-immune stock. We also think that [illegible] in the rate of additions usually—although not [illegible] —diminishes the secular rate of mortality and [illegible] the substitution of an irregular zig-zag curve of mortality for a high and *relatively* constant rate.

Age and Mortality

Passing now to age and mortality, some idea of the nature of events is conveyed by the comparison of the limited expectations of life at entrance of (1) mice under the most favourable conditions; (2) mice under "ordinary" infected conditions, and (3) mice under "optimum" infected conditions. By the first class I mean mice living in a herd under the same conditions as the experimental herds but not exposed to infection. Their expectation is fifty-seven days. By the second I mean the ordinary entrants to herds exposed to aertryckal infection. Their expectation of life is twenty-five days. By the third I mean mice admitted to the last-mentioned herds after artificial immunization by the methods which proved most effective. Their expectation of life is thirty-two days. The maximum span is sixty days, so that the first class enjoyed 95 per cent., the second 42 per cent., and the third 53 per cent. of the maximum possible.

If we consider the course of mortality with age of each of the three types, the results are as follows. For the first class our data are not complete enough to permit of any quite conclusive inference, but it seems probable that "healthy" mice conform reasonably closely to what has been called Gompertz's law of mortality, namely, that the force of mortality (for present rough purposes we may say rate of mortality) increases geometrically with age. It is at least certain that such mice do not exhibit an increase of mortality to a maximum early in life, that is, at an age at all comparable with the epoch of maximum in the second and third classes (see below). These classes contrast with the first in showing a regular and rapid increase of mortality with age to a maximum between the fifteenth and thirtieth day of cage life (the maximum is later in aertryckal than in pasteurellal infections); from this maximum the rate descends more or less smoothly to a level which is thereafter maintained; the trend from about the fortieth to the fiftieth day of cage life oscillates about a parallel to the axis of zero mortality, parallel to that axis but much above it. The maximum of the third class is much lower than that of the second, but sooner or later the curve of the former rejoins that of the latter and, had we only under examination the rates of mortality at ages over 50 days, we should be unable to distinguish the two sets. The advantage derived by pre-immunization is, in respect of exposure to risk, early in cage life. That ultimately the two curves of mortality should approximate is intelligible, but it might, perhaps, have been hoped that the ultimate rates of mortality of survivors should approximate to those of mice not exposed to the infection, that by virtue of active immunization and survival of the fittest we should eventually produce a population of, in a Pickwickian sense, elderly mice fit, like Macbeth, to laugh to scorn the specific dangers of the herd. As in Macbeth's own case, the dangers are rather more complex than appeared.

Selection and Immunization

A first point of interest is how far the relative protection acquired by survivors beyond cage age 30 is a consequence of survival of the fittest or of active immunization We have carried out a series of experiments to determine that question The method was to recruit a herd from two sources One source was ordinary, healthy, quarantined immigrants the other was a set of mice which had survived varying periods in a herd within which the infection (the subject of the experiments) was raging Upon either hypothesis, that of selection or of immunization, the mice which had survived varying periods in the testing herd would be expected to compare favourably with the untested immigrants to the experimental herd in respect of longevity

TABLE I

Cage B All A Mice and all C Mice (Specific deaths only)

	Length of Exposure in Cage A (Days)	Number in Group	Length of Life in Cage B Limited to 60 Days	
C mice	0	887	22 37±0 36	
A mice	10	173	21 34±1 10	All A s 28 43±0 99
	20	163	29 90±1 13	
	30	128	32 99±1 28	
	40 & 45	90	33 08±1 52	
	50 55 & 60	73	37 39±1 60	
	65 70 75 80 90 & 165	58	30 20±1 00	

Difference between A s and C s = 6 07±0 66

We found that the superiority increased with length of survivorship in the testing herd not indefinitely but up to a comparatively early maximum, mice which had survived forty or more days did not succeed better than mice which had only survived thirty days in the testing herd We also found that mice which had been exposed in the testing herd during a period of comparatively low mortality had an advantage over the untested immigrants, less indeed than mice which had lived through more strenuous times in the testing herd, but still quite substantial Hence, on a general balance of the evidence, we concluded that the factor of active immunization was probably more important than that of selection of the fittest in conferring an advantage

TABLE II

A Mice whose time of exposure in cage A was at an average death rate of <0 00750 and C Mice

	Length of Exposure in Cage A (Days)	Number in Group	Length of Life in Cage B Limited to 60 Days	
All C mice	0	887	22 4±0 36	
C mice corresponding to these A s	0	433	20 9±0 49	
A mice	10	59	23 3±1 60	All A mice 25 08±0 84
	20	38	23 8±1 99	
	30	39	25 4±1 97	
	40	30	26 6±2 24	
	50	9	34 6±4 10	
	60	10	33 7±3 89	
	65	9	22 4±4 10	
	70	8	31 25±4 35	
	75	10	14 9±3 89	

Difference between these A s and all C s=2 71±0 92 days
Difference between these A s and contemporary C s=4 2±0 97

I do not, of course, mean to suggest that we attach little importance to innate variations of natural resistance and to the elimination by death of the less resistant, but merely that, in our judgement, the chance factor (as it can be loosely termed) of varying dosage of infection and the actual biological change effected in all or in a large majority of the exposed to risk by previous sub lethal infections, together constitute at least as important a factor of the general situation

Effect of Pre immunization on Animals Exposed to Risk

With respect to the effect of pre immunization on animals exposed to risk—evidently a matter of great practical and theoretical interest—the following table is instructive.

TABLE III

Probability of Surviving Five Days Specific Deaths

Cage Age in Days	E, F, G	Controls	Difference	Column 2 / Column 3	Graduation of Col 2
0	0 9963	0 9925	0 0043	1 004	1 001
5	0 9946	0 9715	0 0231	1 024	1 009
10	0 9879	0 9151	0 0728	1 080	1 029
15	0 9351	0 8291	0 1060	1 128	1 113
20	0 8211	0 6969	0 1242	1 178	1 217
25	0 7164	0 5641	0 1473	1 261	1 274
30	0 6052	0 4875	0 1178	1 241	1 229
35	0 5004	0 3813	0 1191	1 312	1 196
40	0 4019	0 3270	0 0749	1 229	1 161
45	0 3121	0 1984	0 1137	1 573	1 111
50	0 2329	0 1210	0 1089	1 910	1 062
55	0 1786	0 0890	0 0896	2 007	1 020

This herd was exposed to aertryckal infection and the E, F, G mice were effectively immunized before admission It will be seen that their advantage in respect of average chance of surviving during the next five days exposure increases to a maximum about the twenty fifth day of cage life and that the advantage increases to, and declines from, this maximum in an approximately symmetrical way This demonstrates well the very great advantage of pre immunization when the period of exposure to risk is limited For instance, by the thirtieth day only about 30 per cent of controls will survive, of effectively pre immunized mice more than 50 per cent—an immense advantage But the mice which survived to the thirtieth day are much less sharply differentiated and those which survived to the fortieth hardly at all At that age one of the control groups had a limited expectation of life intermediate between the best and the worst of the three pre immunized groups

Commentary

The ultimate approximation of the rates of mortality of the different groups might be explained in terms of many hypotheses I suggest that the simplest is on the following lines It is unlikely that any artificially induced immunity would ever be more effective than that conferred in the ordinary course of herd life upon the survivors of continuous exposure to infection The advantage derived from pre immunization—a very substantial one—is to bring the survivors at a certain date into as good a position as the surviving controls without having made them pay the price in high mortality which occurred in the controls Divide a set of ordinarily intelligent persons into two batches, leave one batch to their own devices, provide the other with good teachers of some subject, and examine both batches at regular intervals, admitting no candidate to a subsequent examination who has been ploughed in the one before We should find the proportion of ploughs in the earlier examinations much higher among the self taught, but ultimately we should expect the percentages to approximate and the quality of the ultimate survivors of both groups to be much the same That in our case the ultimate survivors of both groups still experience a heavy mortality is, I suggest due to the impossibility in infections of this type of raising the standard of resistance above some critical value Neither by pre immunization nor by natural immunization can we produce mice which are impervious to the continued bombardment of infection which the conditions of herd life impose

Summary

The further discussion of this matter would take me beyond the boundaries of statistical analysis and I will conclude by summarizing the points which seem to me well established —

1 In herds of mice exposed to heavy risk of infection of the type we have investigated, the regular addition of

healthy animals, and careful exclusion of new infection, will lead to the perpetuation of the disease through many generations. In small herds the infection may cease, in large herds it will probably be perpetuated indefinitely.

2 We can find no conclusive evidence that environmental, non-specific factors, modify in any significant way the secular course of epidemicity in our herds.

3 Pre-immunization will greatly lower mortality during the early herd-life of the pre-immunized animals. Ultimately the rates of mortality of pre-immunized and naturally immunized animals approximate to a level much above zero. In these infections a solid immunity—namely, an approximation of the specific mortality of the herd to zero—cannot be attained by any method which has so far been tested.

ADDENDUM

Since this opening paper was written we have gained enough experience to authorize us to suggest that in virus infections herd immunity develops on lines other than those illustrated in the bacterial infections we have studied. The kindness of Miss J. E. Marchal, of the National Institute of Medical Research, has enabled us to study in herds the virus disease, infections *Ectromelia*, which she first described in 1930 (*Journ. Path. and Bact.*, 33 *ii.*, 1930, 713.) Miss Marchal discovered this infection in a stock of mice ; it is clinically characterized by an oedematous swelling of a foot followed by gangrene and separation, but often goes on to generalized illness and death. Miss Marchal proved that the essential *materies morbi* was a virus, and that animals which had passed successfully through an attack were very resistant to the injection of virus-containing substance. We have, down to June 30th, 1931, had two herds infected with *Ectromelia* under observation respectively for 224 days and 166 days. In the former 672 mice and in the latter 495 mice have been at risk, and the aggregate mouse-days of exposure were 25,168 and 16,374 respectively.

So far as experience during the early days of cage life is concerned, these heavily infected communities differed in no material way from the similarly treated herds wherein either *Past. muriseptica* or *Bact. aertrycke* was the *materies morbi*. But when the rate of mortality began to decline the fall continued, passed below the asymptotal line which characterized the bacterial infections, and ultimately reached a level differing in no important way from that of the rate of mortality of uncontaminated herds. The table (Table IV) compares the limited expectations of life of *Ectromelia* herds, a *P. muriseptica* herd (P_2), and of a herd not exposed to any infection. The latter, of course, enjoy an expectation which, even at entry, falls but little short of the theoretical 60 (their slight inferiority to mice kept under conditions as nearly ideal as can be realized in captivity is attributable to the fact that, in a large herd, battle, murder and sudden deaths are of more vital statistical importance than in small groups). The *Ectromelia*—and the bacterially—infected herds have expectations of life at entrance less than half the theoretical value, and, as we have already seen, the bacterially infected do n[illegible], at any age, attain a value much above 50 per cent. [illegible]the ideal. By the 50th day of herd life the survivors [illegible]e virus infection are almost on a par with the normal r[illegible]d the evidence suggests that this advantage will n[illegible]t, that the survivors in these highly infected h[illegible]itting unsalted immigrants are as little endar[illegible]heir environment as the parents of children [illegible]n an urban community.

SUICIDE FROM THE SOC[illegible] ASPECT*

BY

SIR HUBERT BOND, K.B.E., M.[illegible]
LL.B.LOND., F.R.C.P.

ONE OF H.M. SENIOR COMMISSIONERS OF THE BOARD [illegible]ROL, AND CIVIL CONSULTANT TO THE ROYAL NAV[illegible].

Suicide, from whatever aspect it is approached, is undeniably an important subject. It is one which for many years has interested me ; and, for a number of years, it has been my habit to collect newspaper cuttings and other records of suicides in the hope that opportunity may present itself to gather together the special points which have occurred to me in the course of their perusal. My collection is quite a haphazard and miscellaneous one, and is much too large to permit analysis of it at short notice for the purpose of this discussion. Without any such analysis, certain points, however, have forced themselves on my notice, of which two or three may be appropriate to this discussion.

SUICIDE A MEDICAL PROBLEM

For instance, the almost complete failure to realize the existence of medical problems beneath every case of suicide, coupled with the fact that most of these problems require for their right handling an adequate knowledge of mental disorders. As a consequence, is that contentment which exists with the present often far from effective procedure; and, with respect to inquests in cases of suicide and to charges of attempted suicide, the further failure to see the place they occupy in problems of Mental Health and the peculiarly valuable opportunity they offer for promoting Preventive Medicine. With rare exceptions, those, in whose hands lie inquests and charges of attempted suicide, not only treat these occurrences as *prima facie* crimes, as is their duty according to present law in England and Wales, but they proceed to treat the parties concerned entirely upon socio-legal lines, and almost invariably ignore or mishandle the medical or psychological aspect. It is not my wish to cast any aspersion or adverse criticism on these men and women either individually or collectively. Quite the reverse. Over and above professional attainments (to praise which on such an occasion as the present would be an impertinence), coroners and magistrates, for these it is who are mostly concerned, we know to be

* Read in opening a discussion in the Section of Neurology and Psychiatry, at the Annual Meeting of the British Medical Association, Eastbourne, 1931.

shrewd, common-sensed and kind; and, even from the summaries of proceedings which appear in the newspapers, it is not difficult to discern either the close and anxious care given to these inquiries, or, in cases of attempts, the kindly efforts to rehabilitate the would-be suicide. All that and much more is willingly granted: my point is that either the psychological aspect is ignored, or it is dealt with by *obiter dicta* which, however well intended, are, in point of fact, often erroneous or else are in the nature of platitudes, and which, while they may deal with the situation for the moment, quite fail to go to the root of the matter. Again I ask not to be misunderstood: I am casting no stones and making no attack upon persons, the difficulties of whose task we, of all people, ought to realize; for these difficulties are part of our daily work, and without thorough training and knowledge of psychological medicine there is no reason to imagine that we should be more effective.

In one particular I should like to lodge an actual protest: namely, against the practice frequently made of putting questions, at inquests or in magisterial proceedings, as to the existence, present or former, of insanity or of instances of suicide in other members of the family. "Evidence must be relevant" is a Rule, the strictness of which in English law might be sufficient, in my opinion, to rule out the admissibility of such questions, especially in the light of the well-known unreliability of statistics relating to family history in mental disorder. Apart from the legal aspect of this point, and however valuable medically such information may be, thus to catechize persons as to insanity or suicide in their family is surely to seek it in the wrong manner and in the wrong place. The practice is, in my view, highly pernicious. It spreads ill-founded, possibly false, doctrines as to the influence of heredity in the causation of suicide and mental disorder; to my own knowledge it sometimes causes deep pain and distress, and is apt to foment a dread of liability to insanity or suicide. This already much too common and generally needless dread should be dissipated at every possible opportunity, as part of mental health propaganda. In truth, I could cite several cases of suicide—and some of my hearers doubtless must know of other cases—in which I am convinced the act was mainly due to the doer's belief that suicidal propensity was inherent in the family; and still more numerous are the cases of mental disorder that I have known, and know now, in which the attack seemed clearly to have been precipitated by unhealthy rumination upon the fact that relatives have been mentally ill, in the light of unwarranted and mischievous statements as to heredity and insanity. Well indeed, with Job, might such patients say—and, in fact, some of them have said to me—"For the thing which I greatly feared is come upon me, and that which I was afraid of is come unto me."

It is, I believe, a fact that, throughout the whole of my collection of records of suicides and attempted suicides, there is not a single instance of evidence of determined and enlightened inquiry as to what steps were taken by the relatives and friends to prevent the occurrence by securing really adequate treatment; nor, in the case of attempts and in discharging the accused, either on his own undertaking or to the care of friends, is there a single instance reported of insistence on adequate medical treatment and inquiry as to where that treatment will be obtained. Alas! were such inquiries made and pressed, too often would it be discovered that means of treatment are far from satisfactory; but that is just where such inquiries could render great service. Under the Mental Treatment Act there is complete opportunity to organize thoroughly effective treatment; and, now that mental hospitals are a charge on county and county borough funds, to provide, should coroners and magistrates desire it, for the attendance of doctors with expert knowledge of mental disorders. The position, as I have ventured to depict it, cannot be regarded as satisfactory. It is not a question of finding someone to blame. We are all of us in our respective spheres responsible. Its rectification is part of the general problem of Mental Health; and, besides the lead and help which the Central Authority can give, and indeed are giving, it can best be dealt with, I suggest, by a Mental Health Committee in each area, formed by a unification, as permitted by statute, of the statutory committees under the Lunacy and Mental Deficiency Acts; and by assigning to it wider powers and duties than those devolving on it under those Acts. It most assuredly should not be approached by any anti-suicide campaign.

Suicide as a Subject for Attention

That, in works on Psychiatry and Psychology, so comparatively brief notice is taken of suicide has been long a matter of astonishment to me; and that it is in need of renewed and much further study from a symptomatological and psychological standpoint I am in no doubt. The truth, I believe, is that it has failed to get the clinical study which other symptoms and disturbances or perversions of instinct have had, because, on return to convalescence or, at any rate, to "accessibility," there have been a fear and unwillingness—groundless and mistaken, in my opinion—to remind the patient of so serious an event as the attempt to commit suicide. In point of fact, this is one of the particularly favourable moments for vigorous psychotherapy. Such study should include, as suggested by Professor Robertson, of Edinburgh, careful inquiry, with the aid of trained social workers, into the environment, circumstances and personal history of a series of consecutive cases, of both suicide and its attempt. Attention on these lines is perhaps rather from the medical and psychological, than the sociological, aspect. In truth, it is not easy to maintain any sharp separation between these two aspects. For the purposes of both of them, and particularly of sociology, we are badly in need of up-to-date and easily accessible statistics of suicide and attempted suicide, related to the statistics of certain social and perhaps cosmic phenomena which experience has shown may have a bearing on them. Such statistics for our own country need careful study in the light of comparable ones for foreign countries and those of the Dominions and other parts of the Empire. With but six weeks' notice of this discussion, the utmost that I have been able to do is to get together and to consider, in the light of earlier figures, some figures for England and Wales belonging to certain years selected because they were Census years.

Let me admit a one-time impression, gathered from general comments in papers and others in relation to individual cases of suicide, that its rate has been increasing with somewhat disturbing velocity, and that a position perhaps was approaching which might demand attention and the consideration of means for its redress. I think, too, that there is a fairly widespread belief to that effect, coupled with the further notion that it is especially the suicides of persons in adolescence and early maturity that are responsible for the alleged rising rate. This implication of adolescents and young adults is certainly not justified; and, while there can be no doubt that, as already stated, the subject of suicide is ripe for much closer medical study than it has received, I greatly doubt whether, at any rate in our own country, it is, or is likely to be, a problem of serious moment. On the other hand, if it can be shown to be a matter for deservedly grave concern in other countries, it rightly behoves us not to over-

look the possibly false security of our own position. In this connection, is it not desirable to emphasize the value that might accrue from giving psychological medicine a place worthy of its importance in the Health Office of the League of Nations?

There are two reasons against the reality of any alleged increasing propensity to commit suicide. First, the intimate relation of suicide to mental disorder, as to which my belief is so firm as to amount to a strong doubt as to the existence of sane suicides. That attitude, I am aware, is contrary to legal doctrine and to the law, and goes considerably further than is taught in text-books on psychiatry; but I feel sure that the more closely individual cases are studied the more it will be realized how difficult, if not impossible, it is to be sure at the time of the act, even if only an attempt, that the doer was not mentally disordered. On this assumption follows my second reason —namely, the stability (approaching, indeed, rigidity) of the ratios expressing certain incidences, in particular those relating to mental disorders. The longer it falls to my lot to examine and to handle yearly statistics of notifications to the Commissioners, the more strongly does this uniformity or stability of ratios impress itself upon me. It has formed one of the principal topics in the short course of William Witherington lectures which it has been my privilege to give this term in the University of Birmingham; and, in its further study and right understanding which I do not think has been reached yet, I feel sure lies the correction of some mistaken beliefs and the key to questions that hitherto have baffled us.

That there is good ground for my scepticism and that the incidence of suicide presents no position for alarm is borne out, in my opinion, from the figures which presently shall be laid before you. It should be remembered that, in speaking of "suicide" and of the "suicidal propensity," consideration should not be limited to the completed act, but should take cognizance of statistics relating to attempts at suicide; and that both these acts are merely the overt phenomena of an urge to commit suicide—a mental condition and a reversal of the *lex nostrae conservationis* itself. Is not this law too elemental and too strong to allow the possibility of any increase in the propensity itself? Maybe the number of suicides and of attempted suicide, or rather their ratios to the population, has varied and will vary. Doubts have been cast even upon the reality of this variation, save within narrow limits, but, assuming its occurrence, the probability of its cause being external and accidental seems to me very great—to be dealt with partly, and mainly, as a medical matter and partly on sociological lines, but not as a

touch upon only the following few references—as being the more important ones.

Statistics concerning suicide can perhaps be said to date from 1750 as to Sweden and 1783 as to Switzerland and Paris. Most of those subsequently published, few of which were earlier than the second quarter of the nineteenth century, were collated into the well-known and remarkable book by Morselli of Turin, which may be said to include all available data up to 1876. For subsequent information upon the subject, especially as regards our own country, various books, papers and articles are available; but no work of anything like its comprehensive nature has appeared since that of Morselli.

It is the frequency of suicide, and of attempted suicide, considered also in relation to sex and age, and to mode of death, to which main attention has been given; but, in relation to its causation, endeavour has been made (evidently at the cost of much patient labour but with not very convincing results) to correlate numerous cosmic and social factors—climate, altitude, barometric readings, phases of the moon, seasons, months and time of day, races, religion, morality, occupation with noteworthy facts as to armies, state of trade, density of population, and the difference between urban and rural life, celibacy and parenthood, alcoholism and heredity, and the relationship to the psychoses. Some of the conclusions savour of the fantastic; others are highly interesting; but, even of the latter, there is no time to touch upon more than two or three.

Facts as to sex, age and mode of death are repeated and confirmed in my own statistics, and will be mentioned with them. My figures do not include attempts at suicide, and it is of interest to note that, in them, the predominance of males (with its average of 3 to 1) is not so marked as it is in cases of the completed act. Of interest, and perhaps of more importance than at first thought would seem likely, is the apparently well authenticated fact that the transitional period between spring and summer in northern countries has tended to show the highest proportion of suicides. To be able to compare these figures with those for New Zealand and antipodal parts of Australia would add to the interest. Instead, however, of the explanations offered for this phenomenon, I should be inclined to suggest that those who uphold the potency of septic foci as a cause of mental disturbance would have, as part of their thesis, a much more understandable theory to offer, and one moreover that can be adequately tested. With either the justification or wisdom of laying stress on heredity as a cause of suicide, I am not in agreement, but there are not wanting

ive years. That he took a gloomy and serious view of he situation is plain from such expressions as—"The errible increase of suicide at the present time" (1879), 'the suicidal epidemic of our age," "the alarming increase of this social calamity" and "this fatal plague of ur age." Were all this not a serious over-statement or xcept there had been in the meantime a gratifying halt n this "plague's progress," it might be difficult to find djectives lurid enough to describe the present position s to suicide in our midst; particularly when we must onfess that, despite the warning some fifteen years earlier n the *Times* coupled with much sound advice, neither as the pace of life, said then (1864) to be excessive, lackened, nor has any of its advice been taken. Need hat seriously disturb us, and may we not take it as a esson not to be too easily moved by alarums? For, since the article was written, the pace of life, or what nost people mean by that expression, has been vastly ccelerated; whereas, so it seems to me, the position with espect to suicide has not altered materially.

INCIDENCE OF SUICIDE IN ENGLAND AND WALES DURING THE PAST 40 YEARS

The comparatively brief time at my disposal during the past six weeks has limited my statistical contribution to this discussion to a statement of the number of suicides which occurred in England and Wales during each of the four Census years 1891, 1901, 1911 and 1921, and during the year 1929. With the help of Mr. G. F. Williams and Mr. E. H. Warland in our Board's statistical branch, these have been set out in age-periods; and, with the exception of those relating to the year 1929, they have been expressed as proportions to each 10,000 of the population, the gross numbers of which have been shown also. Corresponding ratios have not been given for the 1929 incidence because it would have been against only an estimated population that they could have been worked out. Had this discussion been timed for next year or should it perchance then be re-opened, it would be possible of course to contrast the ratios of five Census years; and, with the extra time at our disposal, it would be possible also to elaborate the calculations in several serviceable directions. It is hoped, however, that such figures as there has been time to compile will prove sufficiently impressive to warrant certain deductions, the making of which is much facilitated by the additional five lists, one for each of the Census years and for the odd year, in which the methods adopted for suicide are classified and set out numerically, both in gross and in a percentage to the respective total number of suicides. The special importance and value of looking into the method of suicide adopted will become apparent in the course of my remarks.

The selected age-periods are eight in number, following the precedent of our Board's office which, in the main, is that of the Registrar General. These age periods are: under 15, 15-19, 20-24, 25-34, 35-44, 45-54, 55-64, and 65 and upwards. It will be observed that the first, and especially the last, lend themselves least to comparison with the others; and that, of the other six periods, two are quinquennia and four are decennia, so that for purposes of comparison with the decennia, 15-19 and 20-24 should be grouped together. It, however, at once can be said that the cases of suicide in the period "under 15" are so few—ten boys and six girls in 1891 and, in more or less diminishing numbers down to one of each sex in 1929—that, although no doubt these in all 44 cases of suicide in children afford valuable opportunity for cognate medical study of a most instructive kind, yet for the purposes of my remarks they can be ignored.

Age-periods 15-19 and 20-24

Since they together form a decennium and as the remaining five periods, with the exception of the terminally indefinite one, are decennia, it will be convenient for purposes of comparison to take these two simultaneously. It will be noticed that all the ratios in the later quinquennium exceed those in the 15-19 period except in the cases of three pairs, each of them female, in which there was equality. As between the four Census years (1891 to 1921) and considering the sexes separately, there is a noteworthy approach to equality between the ratios; but the closeness is not so striking in all the later periods, doubtless because the actual number of suicides in these years of adolescence and post-puberty is so comparatively small: only 8.1 per cent. of the total suicides. Thus, the male ratios in the 15-19 period are 0.3, 0.3, 0.4, 0.3, and in the 20-24 period they are 0.7, 1.0, 1.0, 0.6, the corresponding two sets of female ratios being 0.3, 0.5, 0.4, 0.3, and 0.3, 0.5, 0.5, 0.3. By combining the two quinquennia together into the decennium 15-24, the four Census years show 0.5, 0.6, 0.7 and 0.4 as the suicide ratios per 10,000 males; and 0.3, 0.5, 0.4 and 0.3 as the corresponding ratios for women. Whatever increase the ratios of the later age-periods and of the totals may suggest in the incidence of suicide, it is abundantly clear that there was no increase of it among young people. On the contrary, there was during that period of life a tendency for it to decrease: so slightly, however, that the impression left is that the incidence was stationary. The actual number of suicides during 1929, 61 males and 50 females during the 15-19 period and 128 and 72 respectively during the 20-24 period, cannot be expressed yet in ratios; but, except that there has been a notable fall in the total number of persons at these ages, there is no reason to think that the position is less stationary. Before leaving these two quinquennia, it is of importance, in relation to what we shall find in subsequent periods, to note in the 15-19 period how closely, for all four Census years, the male and female ratios approximate to each other—0.3-0.3, 0.3-0.5, 0.4-0.4, and 0.3-0.3: indeed, with one exception, they are identical. In the next quinquennium, 20-24, they begin to diverge and a male preponderance begins to appear—0.7-0.3, 1.0-0.5, 1.0-0.5, and 0.6-0.3. By merging the two quinquennia into one decennium, for better comparison with the four later decennia, the four pairs of male and female ratios then become—0.5-0.3, 0.6-0.5, 0.7-0.4, and 0.4-0.3: this is a numerical preponderance of male suicides over females of about 1.3 to 1. We shall find that, in the next two decennia, it quickly reached 3 to 1; that thereafter it increases, fairly steadily, until in the last period, 65-and-upwards, it is about 6 or 7 to 1; and that the final average is very closely 3 male suicides to every female suicide.

The Four Decennia 25-34 to 55-64 and the Period 65 and Upwards

Nothing will be gained were each of these five periods taken by itself, and, by considering them together, it is, in fact, easier to emphasize the stability, fixedness and almost rigidity of the ratios from Census to Census, and the tendency, after 45 years of age, for the average male preponderance of 3 to 1 to become still greater. The only noteworthy exceptions to this general statement are in the figures of the 1921 Census, where three ratios, both male and female, in the period 25-34, and the male ratio in the period 35-44, show a distinct drop. Thus, in the 25-34 period, the male ratios were 1.4, 1.5, 1.5 *and* 0.9, those for women being 0.5, 0.5, 0.6 *and* 0.4; in the 35-44 period, those for men were 2.4, 2.4, 2.3 *and* 2.0, whilst those for women were 0.8, 0.8, 0.7 and 0.7. Through the remaining three periods they rise with remarkable regularity, except that in the period 65-and-upwards, where the ratios at the four Census years have reached 4.9, 5.0, 4.5 and 5.1 for men, and 0.7, 0.8, 0.8 and 0.8, the latter, instead of a rise, show a reduction when compared with 1.0, 1.1, 1.1 and 1.2 which were the ratios for women in the immediately preceding 55-64 period.

Proportion of Suicides as to Sex

In both the previous paragraphs reference was made to this matter which has its interest, if only because of the attention it has received in previous inquiries and in all countries. In my set of figures, its uniformity of behaviour, clearly noticeable in each of the four Census years, perhaps is best seen in those for 1901. There it can be seen that in the under-15 period the male and female ratios, as it happens, were equal, 0.01 and 0.01; they began to oscillate in the next two quinquennia, with a tendency for the male ratio to preponderate, 0.6 and 0.5, when the period is looked at as a decennium; in the next two decennia they exhibited exactly the average of 3 to 1, 1.5 and 0.5 in the 25-34 period, and 2.4 and 0.8 in the 35-44 period; in the next decennium the male preponderance, 3.7 and 1.0, began to exceed the average, still more so in the 55-64 period, where the ratios were 4.9 and 1.1; until in the 65-and-upwards period, where they were 5.0 and 0.8, suicides in men outnumbered those in women by rather more than 6 to 1.

Ratios for all Ages

The stability and uniformity of the ratios, as probably was to be expected, is still more marked when they are worked out for the totals irrespectively of age-periods. Thus for the four Census years, the ratios of suicides per 10,000 population are 1.3, 1.5, 1.5 and 1.5 for males, and 0.4, 0.5, 0.5 and 0.5 for females; and, for both sexes together, they are 0.9, 1.0, 1.0 and 1.0. It will be observed, too, that the sex proportion is almost exactly 3 to 1.

The year 1929 is the latest for which the number of suicides has been published. They were 3,480 males and 1,504 females. These numbers can be expressed as ratios upon only an *estimated* population. So calculated, they are 1.8 for males and 0.7 for females, and 1.3 taking both sexes together. If these are reliable, which I am inclined to doubt, they show a distinct and noteworthy rise of about 30 per cent. in the suicide rate, more for women than for men, and they show a departure from the hitherto very stable sex ratio of 3 to 1. It is impossible, until the population at the 1931 Census is available in age-periods, to say more as to the reality or otherwise of this rise in the ratios. Assuming there has been a rise, it is, however, quite possible to suggest something as to its nature. This comes out when the means adopted for committing suicide is considered.

Form or Means of Committing Suicide

These have been analysed for me for each of the four Census years 1891-1921 and for the year 1929; and the figures for each form, separately as to sex, have been set out also in percentages of 100 suicides from all forms. The results are highly instructive; the stability and uniformity of the percentages is so marked as to be startling, were it not that attention has been drawn in previous inquiries to a good many of the points which thus emerge. It is to be noted, however, that while the figures and percentages for the four Census years thus closely correspond, those for the year 1929 contain marked differences, and that the commencement of these departures can be recognized in the two Census years 1911 and 1921.

As has been pointed out often, each method of suicide is favoured by one sex more than the other. It, however, has not, I think, been pointed out how marked is this favouritism; that is, that there is no method used at all even-subjevhich comes at all near to an equal division present positiexes. Although this statement does hold vious ascertainmespect to methods of suicide less often

der, as Emerson sa where the figures and percentages are

its duty. This his which seems to me to be of consider-

er and to summarize arked. Thus, crushing and the

s, omitting Biblical, cl which resort is had more by

individual persons, goe om high places used more

of the eighteenth century' suicides and the

instruments; during the four Census years the male percentages were 20.5, 18.6, 20.3 and 21.6, those for females being 13.1, 8.8, 13.6 and 11.2; for the year 1929 there was a marked drop in the extent to which this method was used as respects both sexes—16.7 and 7.9.

Until the new method of suicide by the use of coal gas, between the years of 1911 and 1921, came to be frequently employed, drowning was by far the commonest method adopted by women. Thus, during the four Census years, the male percentages for drowning were 18.7, 17.5, 19.0 and 21.2, whilst those for females were 34.0, 34.2, 33.1 and 32.4; for the year 1929 both showed a very marked drop, namely, to 15.7 and 21.9 respectively. Resort to hanging or strangulation is had habitually more by males than females, the two sets of four percentages being 30.9, 29.3, 27.8 and 24.5 for males and 20.2, 17.7, 18.7 and 16.7 for females; a like marked drop to 19.8 and 9.0 respectively being shown for the year 1929.

Suicide by Solid or Liquid Poisons and Corrosive Substances, Including Poisonous Gas

This is the remaining head in the list of means of suicide. Except at tedious length, it is scarcely possible to set the percentages out as has been done for the other forms, owing to their complication by the coming into fashion of the use of coal gas. The figures of my four Census years indicate that suicide by poisoning has been a fairly favourite method throughout the whole of this period, especially by women: the percentage frequency for the two sexes being about 11 for males and round about 25 for females. In 1901 eight men and one woman committed suicide by the use of poisonous gas, 77 men and 28 women in 1911, 233 and 132 respectively in 1921, and as many as 824 males and 461 females in 1929. Expressed in proportions, 23.7 per cent. of all male suicides and 30.7 per cent. of all the female suicides in 1929 were due to the use of poisonous gas, which has become, by far and away, the most common form of suicide in both the sexes. According to my reading of the figures, its use has not affected the occasional resort that is had to crushing, jumping from high places, firearms and to certain rarer methods; but it has considerably reduced the popularity of all other methods, that is of all the commoner methods. The figures further suggest to me that *resort has been had to the use of coal gas by an appreciable—but not at all an alarming—number of persons who, but for its ready availability and the nature of its action, would not have committed suicide.* With reference to alarmist statements as to the number of young folk who use this method, the figures, to my reading of them, are all against the truth of any such belief. In the period 15-19 there were (in 1929) 14 youths and 12 girls who used this method, and, in the period 20-24, 22 males and 21 females; in other words, at least 95 per cent. of the males and 92 per cent. of the females were 25 years and upwards. It is perhaps of interest to add that between 11 and 12 per cent. of the gas suicides in each sex were in the 25-34 decade, 17.1 per cent. of the males and 20.6 per cent. of the females in the next decade, 26.1 per cent. and 30.4 per cent. respectively in the next, 25.4 per cent. and 18.4 per cent. respectively in the period 55-64, and 15.3 per cent. and 12.1 per cent. in the period 65-and-upwards.

The net statistical result of resort to coal gas as a means of suicide appears to me to have raised what was a very stable and uniform suicide rate of 1.5 per 10,000 males and 0.5 per 10,000 females (or 1.0 for both sexes) to 1.8 for males, 0.7 for females (1.3 for both sexes). It may be that when more details of the 1931 Census figures are available, these proportions will need slight correction; but, from certain anticipatory results which have been kindly allowed me from official sources, I believe it will be found that they are very closely correct.

means the whole of these acts, and probably does not entirely do so to-day

Neither the Suicide rate nor that of Attempts represents the full Incidence of Suicide However great is the accuracy now of the returns, it is not possible to estimate and to include in them the frequency of the urge to commit suicide which is really the true suicidal incidence The number who attempt or complete the act is partly determined by external and accidental circumstances, including ease and availability of some new method of committing suicide, especially if that new method is closely allied to the normal process of sleep

Former rises in Suicide rate position ultimately stationary The suicide rate for England and Wales has shown, ever since statistics have been available, a fairly steady, but nevertheless an ultimately diminishing, rate of rise How far these variations in the rate were due to actual changes in the number of suicides in proportion to the population, or how far they were due to increased accuracy in the returns, it is not possible to say It is, however, noticeable that, according to the returns in the first three Census years of the present century, a position of great stability had been reached thus, the number of annual deaths from suicide in each 10 000 of the population living at all ages was, during each of the years 1901, 1911, and 1921, 1 5 for males, 0 5 for females, and 1 0 for both sexes together [1]

Rise in Suicide rate during the Decade since 1921 There is evidence that, since the 1921 Census and to a slight extent during the previous ten years, there has been a growing tendency to resort to inhalation of coal gas as a means of suicide with the result that some persons have used this method instead of some other means and many more have used it who probably would not have taken their lives otherwise As a consequence, the suicide rate per 10 000 of the population seems to have risen during the year 1923 to 1 8 for males, to 0 7 for females, and to 1 3 for both sexes together These proportions may need slight correction when fuller details are published of the Census figures for 1931

Suicide by inhalation of Coal Gas Poisoning by inhalation of coal gas was the method used with fatal result by 824 males and 461 females in the year 1929 It accounted for 23 7 per cent of male and for 30 7 per cent of female suicides during that year It is now the most frequently used method, the next in frequency being hanging in males and drowning in females Of those who resorted to this use of coal gas, less than 2 per cent (14 cases) of the males and less than 3 per cent (12 cases) of the females were in the 15 19 age period and less than 3 per cent males and less than 5 per cent females were aged 20 24 in other words, 92 per cent were 25 years old and upwards The period of life showing the greatest frequency of its use was 45 54 years of age, in which 26 1 per cent of the male and as many as 30 4 per cent of the female suicides by coal gas took place in no other period was there a higher percentage for either sex Notwithstanding this use of coal gas and a consequent probable rise in the suicide rate, the latter in no sense constitutes a "problem,' nor is the position at all alarming It is however, desirable that consideration should be given to the possibility of rendering coal gas less easy to use as a means of suicide

Doubtful utility of retaining Suicide or its Attempt as a Crime While it is desirable and necessary that the question whether death was due to suicide or not should remain a matter for legal inquiry, it is very doubtful if any good results from retaining either it or attempted suicide as possibly a crime

Need for more thorough Study of Suicide as a Medical Subject Suicide, as a subject, is in need of much greater medical study than it has received, both in this country and internationally In addition to the advantage to Psychological Medicine which such study would afford, it probably would provide the best means of determining how to prevent the occurrence of a considerable number of cases that now take place

Help which Coroners and Magistrates could give Coroners and Magistrates could do much both to direct the object of suicide into proper medical channels of inquiry, and, by such action on their part and by directions which Magistrates may find themselves in a position to give, much could be done to stimulate the provision of out patient treatment of mental illness and of nerve clinics, as contemplated by the Mental Treatment Act It may be desirable to consider how Coroners and Magistrates can be approached upon the matter

[1] This general statement and these proportions tally fairly closely with those summarised in *Elements of Vital Statistics* by Sir Arthur Newsholme (1923 ed pp 306-8) in which particulars are cited from Part III of the Supplement to the Twenty fifth Annual Report of the Registrar General (1921-10) His proportions per million living at all ages were calculated upon a standardised population

THE PSYCHOLOGY OF SUICIDE*

BY

H CRICHTON MILLER, M A M D

HONORARY DIRECTOR OF THE TAVISTOCK SQUARE CLINIC

Suicide is man's great retreat from life He has recourse to it when he feels no longer able to endure suffering in the present or pain in the future It is therefore a failure of adaptation and constitutes a final regression from reality The motives underlying suicidal acts are numerous and complex It is impossible to ascertain them with any degree of certainty unless we are intimately acquainted with the patient's psychic life It is certain that evidence given and conclusions reached in Coroners' courts can be regarded as adequate only in a minority of cases The importance of social influences can easily be exaggerated although such influences are frequently operative It will be convenient to group the motives of the suicide under three headings —

(1) Physical pain including frustration of instinctive demands

(2) Social sufferings and fears

(3) Doubts and dreads pertaining to the hereafter

Pain and Frustration

In the first group we have the suicides due to physical pain It is commonly agreed that this causes far fewer suicides than one would expect Halbwach places it ninth in his list of twelve major causes It is also noteworthy that acute pain does not seem to drive men to self destruction as frequently as some of the gross discomforts The pain of trigeminal neuralgia is said to be accountable for a few cases, but it is probable that the incessant discomfort of tinnitus aurium is a more prolific cause Still more noteworthy is the fact, which is not likely to be contested, that men commit suicide more frequently on account of anticipated pain than actual suffering, however acute I imagine that few women have committed suicide when a malignant tumour of the breast was diagnosed, yet there are an appreciable number I believe, who when they observe a nodule in the breast are so terrified that it will prove to be cancer that they take their lives It is difficult to obtain any data about war cases but my impression is that very few wounded men took their lives however acute their suffering on the battlefield On the other hand it is quite certain that of the unwounded who committed suicide many did so from dread of a painful death

We are probably justified in concluding at any rate for civilised man that he is more capable of adjusting to physical pain than to anticipatory dread of it And this

* Read in opening a discussion in the Section of Psychological Medicine at the Annual Meeting of the British Medical Association in Leicester, 1931

conclusion brings up a somewhat analogous phenomenon in a different field. The fear of insanity certainly deserves to rank among the major causes of suicide. In the pre-psychotic stage a man may pass through a phase of tendency to suicide and may even attempt it. Yet when the psychosis declares itself in a delusional manifestation the suicidal tendency may pass completely. To put it in another way, loss of insight allays the mental distress that previously impelled the patient towards suicide. The man who could hardly adjust himself to life with the shadow of insanity upon him can adjust himself to life when he is insane by reason of the insanity itself. This is one example that shows how superficial is the popular view that suicide is evidence of insanity.

In this first group that we are discussing I have included "frustration of instinctive demands." It is probably true that more suicides have been occasioned by thirst than by hunger. It is very certain that when hunger and thirst are both extreme it is only the latter that counts.

But in normal civilized life it is the sex instinct which meets with most frequent frustration and which in consequence accounts for the largest number of suicides in this group. In the first place there is the unmarried woman who feels she can no longer endure the pangs of sex starvation. There must be, I imagine, a few married women, who, on account of dyspareunia or conjugal taunts of frigidity, determine to escape from marriage and therefore from life. I have known at least one woman who gave this as the reason for her attempted suicide. Sterility may perhaps drive a few women to despair. I have never come across an attempt, but one patient, who was bitterly disappointed by her sterility and who knew that her husband was almost as greatly distressed, discussed with me in the most detached way the possibility of suicide, basing her contention on her husband's right to marry a woman who could make him a father.

Both men and women commit suicide on account of homosexuality. But in these cases the issue is almost always confused and can rarely be classed as mere instinct frustration. Conflict over homosexual tendencies in themselves, fear of social discovery, repressed inferiority for not being as others are—these and similar factors come into the etiology. The factor of the exhibitionist suicide is hard to evaluate. We are all familiar with it in the half-hearted suicidal attempts of the hysteric, but there can be no doubt that it contributes to not a few determined and successful suicides. This factor of pose recalls a case cited by Fraser. A rejected suitor in Vienna craved a final interview with the object of his affection. When they met he asked her to return the engagement ring. He placed it over his heart, the muzzle of his revolver against it and shot himself. The ring was found imbedded in the myocardium! Surely a dramatic exit of this type can have been little influenced by instinctive or other basic motives!

In men the factor of sex-frustration probably counts less than in women. The main reason for the difference is manifest, namely, that man has his sexual destiny much more in his own control than has woman. The incidence too is different. With the male the problem tends to be acute in late adolescence and early senescence. With woman on the other hand it is in the late thirties that despair is likely to seize her. Judging from analytical experience one would feel inclined to surmise that many of the suicides of males in the early twenties are due to sex conflict mainly centring on hypogonadism. The feeling of not experiencing sex impulses that one's fellows claim to experience; the haunting doubt as to whether one will ever be able to fulfil the role of the husband; the horror of being revealed as an imperfect man—these things are so often described in the course of analysis that they must surely enter into the motivation of many suicides. In this connection it is important to recognise the passive suicide by starvation. We call this, inappropriately enough, anorexia hysterica; sometimes it is dysphagia hysterica. It should be regarded not as a psychoneurosis but as a definite pre-psychotic suicidal equivalent. It is essentially the great retreat of the late adolescent, and in my own experience it is invariably associated with evidence of hypogonadism. The following case illustrates these points.

A youth of 21, well over 6ft. in height and weighing less than 7 stone, collapsed on a motor-cycle run. He was then in his second year at the University. He had actually begun compulsive abstinence when he first went to his public school. This was the result of an auto-erotic conflict and some ill-judged statement in a pamphlet about sex. When he left school the compulsion gained strength, and by the time of his collapse he had reached a dangerous state of inanition. He was taken to a nursing home on a stretcher; his extremities were profoundly cyanosed. On investigation the acuteness of his sex conflict was revealed. His fear of sex experience was extreme. After a few days in the home he mutilated his penis with a pair of nail scissors to the extent of requiring three stitches. Subsequently he recovered completely and is now both a husband and a father.

This case shows well the way in which many a young suicide retreats from life because of sex fear, and attempts to terminate his existence as a generalized castration reaction. And just as the self-mutilation may be expiatory or self-punitive, so the compulsive abstinence has the same origin.

The climacteric suicides in males are generally attributed to insomnia. The high degree of respectability which belongs to this complaint makes it an eminently suitable explanation for mourning relatives, coroners and journalists. It is however a very unsatisfactory explanation for the psychopathologist. The cases of which he may have accurate information are not infrequently cases of early impotence associated with aggravating emotional factors—for example when a middle-aged man has married a young wife, or when the man attributes his impotence, rightly or wrongly, to a venereal infection in youth, and so on.

Social Sufferings and Fears

Passing on to the second group—social sufferings and fears—we find a large number of cases in which the motivation is much simpler and less liable to misinterpretation. The men who commit suicide on account of bankruptcy, or because they have lost their employment, or in the face of legal proceedings which will expose their misdeeds—all these are familiar enough and reveal the extent to which herd values may eclipse the instinctive desire to live. In many cases one sees only an exaggerated self-love incapable of accepting social humiliation at any price. In others there may be a factor of remorse for wrongs committed, and an impulse towards expiation. Among women illegitimate pregnancy is probably one of the chief causes of the social suicide.

In this connection we may take a special group, difficult to classify, namely, the suicides by identification. Usually the impulse reveals itself by depression and a phobia of committing suicide. A man in the early forties will gradually become depressed, confess that he fears he may do away with himself, and then add, "You see, my mother took her own life when she was 45." In such cases the underlying motive is based on an unconscious feeling that it would be disloyal to the beloved parent to outlive her. The conscious version is "I have inherited from my poor mother a suicidal tendency at the age of 45."

DOUBTS AND DREADS

Finally we come to the last group—doubts and fears of the hereafter. These feelings tend to have an inhibitory effect, but that effect wanes as dogmatic religion, embodying a system of eternal rewards and penalties, loses its hold on the community. In some social systems self-destruction is, under certain circumstances, regarded as a virtuous act liable to secure eternal advantages. In Christianity suicide has been uniformly denounced. But even so there are a certain number of suicides with a religious significance. Sometimes the father complex demands an act of self-punishment whereby alone the individual feels that it will be possible to face the divine Judge. Sometimes the suicide is Messianic in character, a supreme sacrifice of the total personality for some redemptive purpose. Sometimes the compulsion towards purification based on a guilt complex develops into a suicidal act.

In the short space available there is no possibility of dealing with many other important aspects of this subject. The frankly psychotic suicides—especially the melancholics and cyclothymics—are primarily problems of supervision rather than of active therapy. The groups described cover the majority of cases that occur among those who still rank as sane.

SUICIDE FROM THE MEDICO-LEGAL ASPECT*

BY

W. NORWOOD EAST, M.D., M.R.C.P.

ONE OF H.M. COMMISSIONERS OF PRISONS

Suicide connotes to the legalist a crime and to the physician a state of emotional disorder. It was originally an ecclesiastical offence but was transferred to the King's Courts when the separation between ecclesiastical and civil courts was completed, and judge and bishop no longer sat together in court to hear cases.

Bracton, who wrote on criminal law in the early part of the thirteenth century, records that a person who committed suicide in order to avoid conviction for a crime forfeited his lands. Other suicides forfeited their goods only. According to Stephen this distinction was forgotten before the time of Staundforde, a judge in the reign of Queen Elizabeth, who published a work on the Pleas of the Crown.[1] In other respects the law remained unaltered till 1870 when forfeitures were abolished (33 & 34 Vic. C. 23).

There appears to have been no legal authority for the ancient custom of burying a person, against whom a coroner's jury had found a verdict of *felo-de-se*, at four cross roads with a stake driven through the body. Stephen[2] suggests that it originated, like gibbeting, without legal warrant in circumstances now forgotten. It was abolished in 1823 by a statute (4 Geo. 4. C. 52) which enacted that thenceforth it should not be lawful for any coroner to issue his warrant for the interment of a *felo-de-se* in any public highway. He was to order the body to be buried privately in a churchyard, or other burial ground, without any stake being driven through the body, between nine and twelve at night, and without any religious rites. This statute has been repealed by the Interments (Felo-de-se) Act 1882, which provides that the body may be buried in any way authorized by the Burial Laws Amendment Act 1880, that is without religious service or with such Christian and orderly religious service at the grave as the person having charge of the body thinks fit.

Suicide, in English Law, is a felony, self-murder, and the distinctions between murder and manslaughter have been said to apply to this, as far as they are applicable, as well as to the killing of others.[3] But there is no such offence as self-manslaughter (R v Burgess), and Stephen quotes authorities to show that the true definition of self-murder seems to be where a man kills himself intentionally, and according to Hale, also accidentally, if by an act amounting to felony: as when a man striking at another and intending to kill him misses and strikes himself. Conversely if a person, in making an attempt to kill himself, should accidentally kill any of the bystanders, he will be guilty at least of manslaughter, and in most cases of murder.[4]

The abetment of suicide may be as great a moral offence as the abetment of murder, and if two persons encourage each other to self-murder, and one kills himself, but the other fails in the attempt, the survivor is guilty of murder of the other; and if one person encourages another to commit suicide and is present abetting him while he does so, such person is guilty of murder.

A modification of the former principle is suggested sometimes in suicide pacts. In a recent trial at the Old Bailey a man was acquitted of murder: he was found lying with a woman on a bed in a gas-filled room with a gas tube between their heads, and the women died. Wright J. while reaffirming the legal doctrine suggested that it was a law which Parliament might well alter. There is no doubt, however, that sometimes the survivor enters into a suicide pact to free himself from responsibilities he refuses to accept. In connexion with the second principle it may be observed that at the last Liverpool Winter Assize the prosecution alleged that a girl, whose body was found mutilated on the railway line, committed suicide after agreement with the accused, and MacKinnon J. ruled that as the survivor of a suicide pact must be present when the other dies in order to support a charge of murder counsel must confine themselves to the charge of being an accessory before the fact.

The blameworthiness of suicide has been a frequent matter of dispute among lawyers and medical men. Stephen considered that it would be a pity if Parliament were to enact any measure tending to alter the feeling with which suicide is, or ought to be, regarded. Dr. Mercier held that a suicide committed an offence if and when by his act he evaded obligations to the State, or to individual members of the State. He considered also that there were other circumstances that would make the act an offence, as when an epidemic of suicide, restricted to women, occurred in Edinburgh in the sixteenth century, and ceased when it was proclaimed that in future the bodies of the suicides would be exposed naked in the market place.[5]

A person who insures his life while *compos mentis* and later dies by his own hand forfeits the contract of insurance if the coroner's jury return a verdict of *felo-de-se*, on the general principle that a man may not profit by his own criminal act.[6] But if the act of suicide takes place when the assured is insane, then, whether he be beneficially interested in the insurance or not, the policy is not avoided, unless the contract contain a special condition inserted with a view to meet such a contingency.[7] Many modern policies however provide that in the event of suicide during insanity the policy shall be treated as surrendered, and the surrender value paid to the personal representative or other beneficiaries. Cases of this nature are of particular interest to medical men as it may be disputed on the one hand that the deceased committed suicide, and on the other that he was insane when he committed the act.

A coroner may hold an inquest on a body without a jury subject to certain exceptions,[8] but he cannot, sitting

* Read in opening a discussion in the Section of Neurology and Psychological Medicine at the Annual Meeting of the British Medical Association, Eastbourne, 1931.

alone, return a verdict of *felo-de-se*. Both coroners and juries usually attribute suicide to insanity, and out of 4,846 inquests on suicides in the year 1928 the verdict of *felo-de-se* was only returned in 88.[9] But although the memory of the deceased may be so relieved from the stigma of a crime his relations may be burdened with an unnecessary dread of insanity. If the alternative verdict to *felo-de-se* was "suicide the result of mental illness" the modern outlook and phraseology of the Mental Treatment Act, 1930, would be represented.

An analysis of 1,000 consecutive cases of attempted suicide examined by me some years ago showed that only about one-fifth were certifiable as insane, and the experience gained by the examination of more than 2,000 additional cases confirms this view. But many patients suffer from temporary mental disorder at the time of the attempt, and mere trivialities often cause determined attempts at suicide.

An attempt to commit suicide by a person of sane mind, being an attempt to commit a felony, is in law an indictable misdemeanour, and the offender may be committed for trial at the Assizes or Quarter Sessions, and is punishable under the provisions of the Hard Labour Act, 1882 by imprisonment with hard labour. The case can be dealt with also in a court of summary jurisdiction with the consent of the accused.[10] The suicide must be of sound mind and have attained the years of discretion (1 Hale P. C. 411; 3 Inst: 54), therefore, it is no crime for a person to take his life before reaching that age. The mere fact of drunkenness is no excuse for the crime of attempted suicide, but it is a material fact for the jury to consider before coming to a conclusion whether the accused really intended to destroy his life (R v Doody).

The number of cases of suicide and attempted suicide reported to the police are affected probably by many factors. No doubt the increased sobriety of the community during recent years, the receipt of unemployment benefit, trade depression, and the modern policy not to take proceedings in cases of attempted suicide unless detention for a time is in the interest of the person, or for other sufficient reason, operate in one or other direction. And although the number of persons coming before the courts on this charge in 1928 was considerably more than double the average number in the years immediately preceding the war, the number of persons now sent to prison for this offence is about halved. Many of these recognize that they need care and supervision, but would be unwilling to remain for a sufficient period in a mental hospital as voluntary patients under the Mental Treatment Act, 1930, and are ineligible for detention as temporary patients under Section 5 of the Act. And as they cannot be certified, a short term of imprisonment under medical care is inevitable sometimes: it is usually accepted with equanimity and often with gratitude.

The mental condition of an accused person charged with attempted suicide is frequently a matter for special consideration in a criminal trial. In the summary courts an insane person is usually dealt with by transfer to a Public Assistance Institution or private mental hospital. If the Grand Jury at Courts of Assize or Quarter Sessions ignore the bill of indictment the accused is forthwith released from the custody of the court whatever his mental condition may be. If, however, he is found to be insane on arraignment or guilty but insane he is sentenced to be detained during His Majesty's Pleasure. A plea of guilty is sometimes made in order to avoid this, and if the court is satisfied with the medical evidence the prisoner may be considered a proper person to be detained in a mental hospital. A recent decision of the Court of Criminal Appeal is of interest in this connexion. The appellant after pleading guilty to an offence at Liverpool Assizes in May 1929 entered into a recognizance to be of good behaviour for two years, and to remain in a mental institution until he was discharged. The breach of recognizance with which he was subsequently charged, and for which he was sentenced to ten months imprisonment, consisted in his escape from the institution. At the time when he entered into the recognizance he was a certified lunatic, and the Court of Criminal Appeal held that the certificate raised a presumption of insanity which prevented the recognizance from being binding on the appellant, and that there had been no evidence to displace that presumption. The Court allowed the appeal and quashed the sentence (R v Green-Emmott).[11]

The association of murder with suicide is important. The Criminal Statistics for England and Wales in the years 1927 and 1928 show that one murderer out of four commits suicide—66 out of 234. The figures of attempted suicide are very similar, for in a series of 182 persons convicted of murder, whose mental condition I examined, 41 attempted suicide in connexion with the crime. The suicidal act is due sometimes to the certainty of conviction and to the desire to end an intolerable situation. It is also the result of insanity, and Dr. H. P. Foulerton informs me that of 527 admissions to Broadmoor during the last 20 years following charges of murder, 149 attempted suicide at the time of the crime.

In some insane persons the suicidal intention precedes the homicidal; thus the altruistic melancholiac having decided to kill himself first kills his wife to save her from disgrace, suffering, or the necessity to fight the world alone. But the homicidal intention precedes the suicidal in many senile, alcoholic, and delusional murderers and may result from vindictiveness, revenge or hate based on insane beliefs and false premises.

Bogus suicides appear to be uncommon in free life but are sometimes staged in an attempt to defraud an insurance company or for another purpose. Feigned attempts at suicide are made in prison for ulterior gain also; they constitute nearly 70 per cent. of the attempts and are of medical importance as they sometimes miscarry and end fatally.

VERTIGO IN SUPPURATIVE CONDITIONS OF THE MIDDLE EAR*

BY

F. W. WATKYN-THOMAS, F.R.C.S.

SURGEON, CENTRAL LONDON THROAT AND EAR HOSPITAL

Vertigo is defined as "a disordered condition in which the person affected has a sense of whirling either of external objects or of himself, and tends to lose equilibrium." (O.E.D.) It may be due to a variety of causes, labyrinthine and non-labyrinthine, but labyrinthine vertigo is by far the more common.

It is generally believed that normally both labyrinths are in a state of equal tonic activity and send continuous

* Read in opening a discussion in the Section of Oto-Rhino-Laryngology at the Annual Meeting of the British Medical Association, Eastbourne, 1931.

impulses to the higher centres. If both labyrinths are stimulated equally, however great the stimulus may be, there is no vertigo; the slightest difference in stimulation between the two labyrinths immediately produces vertigo. Labyrinthine vertigo is the result of unequal activity of the two labyrinths. The most common cause of such inequality is some affection of the ear, which may be non-suppurative or suppurative. Between these two kinds of vertigo there is a distinction literally vital. Aural vertigo of non-suppurative origin may make a patient's life a burden to him; aural vertigo in the presence of suppuration may mean that his life is in danger.

I propose to confine myself to vertigo associated with aural suppuration. In these conditions we are concerned with the perilymphatic space. The only barrier between perilymph and endolymph is the flimsy wall of the membranous labyrinth; therefore, if the perilymphatic space is invaded, we are justified in assuming that the endolymph space will also be invaded. The perilymphatic space communicates with the cerebro-spinal spaces by the pia-arachnoid sheath of the eighth nerve and by the aqueduct of the cochlea; the endolymphatic space is not in communication with the cerebro-spinal space, as the saccus endolymphaticus lies between the layers of the dura. Thus any infection of the perilymphatic space puts the patient's life in immediate peril.

The perilymphatic space is separated from the middle ear and its accessory cells by two layers, the dense bone of the labyrinth wall and the lining endosteum. At the fenestrae the bony layer is absent, and the only barrier is the endosteum, reinforced at the fenestra ovalis by the footpiece of the stapes. It may be laid down as a rough clinical rule that, so long as the barrier is adequate against invasion the signs will be due to irritation of the affected labyrinth; once the barrier is passed and the perilymph space invaded there will be a brief period of intense irritation followed by destruction, and all signs will then be due to the unopposed activity of the healthy labyrinth.

When vertigo occurs in the presence of suppuration it is probably due to the suppuration, but we must not overlook the possibility of some independent cause—for instance, a patient with a suppurative otitis media on one side may suffer from vertigo which has been produced by blockage of the eustachian tube on the side which has been regarded as normal. On the other hand vertigo must never be attributed to "neurasthenia" or "bilious attacks." Vertigo can certainly cause neurasthenia; under modern traffic conditions a sufferer from vertigo is in danger of his life whenever he crosses a street, and certainly the neurasthenia can aggravate the vertigo, but it is very doubtful if it can ever cause it. Vertigo is often associated with severe nausea and vomiting, but the most intense gastric disturbance cannot cause vertigo. "Gastric vertigo" is a term that should never be used. We still see cases of acute suppurative labyrinthitis which have been diagnosed as "bilious attacks."

In vertigo due to aural suppuration past or present we can distinguish three principal groups of cases:

1. Cases where the labyrinth wall is intact.
2. Cases where the labyrinth wall has yielded to infection to a greater or less degree—the labyrinthites.
3. Cases where infection has reached the posterior fossa—cerebellar abscess—retro-petrous abscess.

WHERE THE LABYRINTH WALL IS INTACT

These cases are characterized by increased irritability of the affected labyrinth. This may be due to: (a) Changes of pressure at the fenestrae; (b) abnormal sensibility caused by exposure of the inner tympanic wall.

Changes of Pressure

Ankylosis of the ossicles. Dundas-Grant and others have described cases in which vertigo was caused by malleo-incudal ankylosis. The probable explanation here is that the stapes is driven in and thus the normal give-and-take between the fenestrae is altered. This alters the intra-labyrinthine pressure and so disturbs the balance between the two labyrinths. Similar phenomena are observed in unilateral eustachian obstruction, as has been described by Sydney Scott.

Fluid or granulations in the middle ear may alter the play of the fenestrae in the same way as an ossicular ankylosis. In these cases the proper treatment is to provide drainage or to remove the ossicles by one or other of the mastoid operations.

Abnormal mobility of the stapes can cause vertigo by irregular alterations of pressure in the affected labyrinth. Such cases are not uncommon in congenital syphilis, but they are fortunately rare in suppurative or post-suppurative conditions. If the stapes is loosened during active suppuration, invasion of the labyrinth usually follows. If the stapes is loose when suppuration is extinct (for example, after a radical mastoid operation) it is possible that we might be driven to destroy the labyrinth. This will be discussed later.

Abnormal Sensibility due to Exposure of the Inner Tympanic Wall

This condition is sometimes found with a large dry perforation of the membrane, and more often after a radical mastoid operation. Vertigo is usually caused by sudden changes of temperature, especially a cold wind. The unprotected inner tympanic wall is cooled and the victim endures an unregulated "cold caloric test." One patient of mine with a large radical cavity, suddenly fell down with a violent attack of vertigo when walking along an exposed sea-front on a cold and windy night. As a rule the condition can be remedied by closing the meatus with a plug of greased cotton wool. This condition may be a danger if the patient swims or dives, the sudden rush of cold water may cause a "caloric response" which completely incapacitates the victim.

If the patient is seen during an attack considerable relief is often given by painting the promontory with 5% cocaine and packing the meatus with gauze or wool soaked in warm paraffin. Accumulations of cerumen or débris in the cavity are often responsible for the attacks. An important point in these cases is that the patients are often abnormally sensitive to sudden falls of blood pressure. Ephedrine is useful in meeting this emergency. Of other drugs chloretone and luminal are sometimes useful, and Dundas-Grant has obtained good results with small doses of quinine, which is believed to diminish the labyrinthine activity.

As a rule in these cases of labyrinthine hyper-sensitivity after a radical operation the condition gradually passes off and compensation between the two sides is reached. Occasionally this does not take place, and the patient's misery makes us consider the advisability of destroying the labyrinth. This may be necessary as a last resort, but only as a last resort. However severe the vertigo may be it is not dangerous to life, and opening an uninfected labyrinth in an ear that has been infected, even though the infection appears extinct, is accompanied by a certain degree of risk, slight it is true, but present. Probably the simplest and safest method is that suggested by Mollison, opening the external canal at the torus, and injecting alcohol into the vestibule through the opening.

If, in spite of an adequate radical operation, granulations persist on the inner tympanic wall and vertigo continues, the probability is that there is a labyrinthine infection.

Lastly we must remember that there is no reason why a patient with a radical mastoid cavity should not suffer from Ménière attacks entirely independent of his suppurative condition. On the law of averages it is unlikely, but the possibility must not be overlooked.

Where the Labyrinth Wall has Yielded to the Infective Process

This group comprises all cases of labyrinthitis of suppurative origin. In these cases we are faced by an entirely different situation. As has already been stated, once the labyrinth has been invaded by a septic infection the free communication between the perilymph and the cerebrospinal fluid implies the risk of spread to the subarachnoid space and consequent meningitis. Labyrinthitis of septic origin, therefore, is a surgical problem, and the suitable surgical solution is determined by the extent to which infection has advanced. Thus in any septic labyrinthitis vertigo and other labyrinthine symptoms are important only as indications of the degree of invasion of the affected labyrinth.

The whole sensory area of the labyrinth is so small that we are entitled to believe that invasion of the labyrinth cavity must quickly cause destruction of the labyrinth function. From this it follows that so long as the labyrinth preserves any trace of function it is unlikely that the cavity is infected, and until that infection is complete the risk to the patient's life is very small.

Varieties of Labyrinthitis

The usual classification of the different forms of labyrinthitis is admittedly faulty, especially in the inaccuracy of the terms employed, but it usefully emphasises important clinical distinctions. Three principal varieties are recognised: (1) Circumscribed labyrinthitis; (2) serous labyrinthitis; (3) diffuse suppurative labyrinthitis, which may be either (a) "latent," or (b) "manifest."

It is possible that an infection of the lumen of a canal might be localised by adhesions, but in practice circumscribed labyrinthitis usually means an incomplete breach of continuity of the labyrinth wall without invasion of the lumen. The bony wall may be eroded until the endosteum is exposed, but as soon as the endosteum is penetrated invasion of the cavity follows, and the characteristic features of the condition are lost.

This probably corresponds to the "sympathetic" effusions into serous cavities. It may be regarded as an inflammatory reaction to a septic process outside the labyrinth. The labyrinth wall has remained as an adequate barrier against the invasion of organisms but has been traversed by the toxic products of infection. Such entrance might be made through the fenestrae or through endosteum exposed by erosion of the bony wall.

Diffuse suppurative labyrinthitis is the result of microbic invasion of the cavity.

In acute suppurations of the middle ear the invasion is usually through one of the fenestrae, either by destruction of the membrana secundaria of the fenestra rotunda, or by loosening of the footpiece of the stapes. It is stated in the textbooks that infection through the fenestra rotunda is the more common; in the few cases of invasion through a fenestra which I have seen this has not been the case, the invasion has been through the fenestra ovalis. Occasionally in acute suppurations, especially in those due to the pneumococcus mucosus capsulatus, infection has entered through an erosion on the torus of the external canal. In chronic suppurations invasion usually takes place through an erosion made by the growth of cholesteatoma. Such erosions are more common on the external canal, but are occasionally found on the promontory. The course of the disease differs according to the site of invasion. If infection enters through the promontory or the fenestrae the main cavity of the vestibule is attacked at once, and destruction is much more rapid than when the infection enters by the narrow lumen of the external canal. For this reason suppurative labyrinthitis is more dangerous in the acute middle ear suppurations than in the chronic. This accounts for the fact that in the acute suppurations meningitis is more common than intracranial abscess.

The distinction between "manifest" and "latent" labyrinthitis is entirely clinical. While the signs and symptoms of recent destruction exist the labyrinth is "manifest," when the affected labyrinth is paralysed and the labyrinth of the other side has taken over all the vestibular functions of equilibration, that is to say, when compensation is complete, the labyrinthitis is "latent." Some cases of so-called "latent labyrinthitis" would be better described as "residua of obsolete labyrinthitis," for the whole cavity of vestibule, cochlea and canals is filled with fibrous tissue. Other cases are really labyrinthine necrosis; the greater part of the labyrinth wall lies as a sequestrum in an abscess cavity in the petrous. In other cases the labyrinthine cavity remains, filled with pus and granulations, an ever-present danger to the adjacent meninges.

We have stated a preliminary axiom that, so long as the infection has not reached the perilymphatic space, the signs and symptoms will be due to irritation of the affected labyrinth; when the perilymphatic space is invaded there will be a brief period of intense irritation followed by destruction. As the destruction proceeds signs are more and more due to the unopposed activity of the healthy labyrinth. When the destruction is complete the surviving labyrinth assumes double duties and we have the stage of compensation of "latent labyrinthitis."

Of the signs that enable us to diagnose between the different forms of labyrinthitis, excepting always the "latent," vertigo is the most prominent. This must not be taken as implying that our decision can be based on the vertigo alone; it is a subjective symptom and the evidence that it affords must always be rigorously checked by the labyrinth tests and examination of the nystagmus and of the alterations in hearing.

Of the labyrinth signs the slow, or labyrinthine component of the nystagmus, the pointing error, and falling are away from the more active labyrinth. The quick, non-labyrinthine component of the nystagmus and the direction of the sensation of falling or movement during vertigo are towards the more active labyrinth. This may be stated as a general rule, but the sensation of the direction of vertigo is unreliable. During the stage of destruction the vertigo is so severe that the patient often describes the sensation as one of being "thrown about" without any particular direction of movement. This is probably due to the combination of irritation and paralysis at this period.

More important than the direction of sensation are the periodicity of the vertigo, either continuous or intermittent, and its severity.

In circumscribed labyrinthitis as the perilymph space is not invaded the signs are those of irritation; the affected labyrinth is often hypersensitive to the caloric test, hearing is affected only by the casual middle ear lesion, and vertigo is intermittent and rarely severe. The attacks of vertigo are sudden and transitory, often brought on by sudden movements of the head and accompanied by a brief nystagmus, usually directed to the affected side. If the lesion progresses until there is an erosion of the bony wall with exposure of the endosteum

of the canal the "fistula sign" can usually be elicited. Under this term we may include all conditions in which sudden changes of pressure in the external auditory meatus —as, for example, pressure on the tragus or suction by a Siegle's speculum—produce vertigo and nystagmus. The reaction is produced by the transmission of the pressure to the perilymph and so to the endolymph. Movement is started in the endolymph and the endolymph wave stimulates the sensory endings of the cristae or maculae as the case may be. It is a clinical application of Ewald's experiment.

Two points in connection with the fistula sign deserve special mention:

1. The presence of the "fistula sign" is positive proof of the activity of the affected labyrinth. It follows that the term is a misnomer, for if there was a true fistula the lumen of the canal would be invaded and destruction would quickly follow. If the "fistula sign" can be obtained it is safe to say that the endosteum is intact.

2. It is seldom possible to diagnose the site of the erosion from the direction of the nystagmus and vertigo produced by the "fistula test." We may hazard a guess but it is no more, and is usually wrong.

Serous labyrinthitis is characterized by the prolongation of the irritative stage and the incompleteness of the paralytic stage. The preponderance of irritation or paresis depends on the degree of permeation of the labyrinth wall. It may be said that in all cases of serous labyrinthitis there is a well marked irritative stage. This is emphasized by Baldenweck, who points out that the more usual nystagmus of a serous labyrinthitis is towards the affected side, that is to say a nystagmus of irritation. Vertigo is always present during the earlier stages of serous labyrinthitis, and at this period a fistula sign is sometimes found; this is to be expected as serous labyrinthitis is often a sequel to the circumscribed form. But the vertigo, though troublesome, is rarely severe, often it is only noticed during movement, and the fistula sign when present is never as dramatic as it is in true circumscribed labyrinthitis. The most likely reason is that although the labyrinth in the early stage of a serous labyrinthitis is unduly irritated it is not really even normally irritable. The irritation is due to the increased stimulus of the intralabyrinthine effusion, which overcomes the commencing paresis. This explains the paradox that a labyrinth showing signs of irritation often shows also a diminished sensitivity to the caloric tests. It will be remembered that an analogous reaction is sometimes found in cases of the so-called "Ménière syndrome." When the irritative stage of a serous labyrinthitis passes off the subjective symptoms often disappear. The labyrinthine paresis may advance so gradually that the sound labyrinth never exerts itself violently. Compensation is acquired gradually and without discomfort. The labyrinthine functions of the affected side, cochlear and vestibular, are diminished but never lost, and traces of hearing and vestibular activity survive.

Diffuse suppurative labyrinthitis presents a very different picture. The irritation is short but violent, and the swiftness of destruction allows no compensation before the full activity of the healthy labyrinth comes into play. Thus the vertigo is of the utmost intensity, continuous and prostrating, usually accompanied by nausea and vomiting. The slightest movement of the head accentuates the victim's distress. A patient once told me that it surpassed the most violent miseries of seasickness. Anyone who has seen a case of diffuse suppurative labyrinthitis in the stage of invasion can understand the cryptic statement that in the Wide-Awake Club of which Mr. Jorrocks was recorder "no member was drunk if he could lie without holding." The vertigo may be so violent that the subject feels as if he were being "thrown out of his bed."

Vertigo gradually passes off when destruction is complete, but until full compensation is reached transitory attacks may be brought on by sudden movement. It is a clinical observation, which is not easy to explain, that compensation occurs much more rapidly if the affected labyrinth is opened and drained, even though prior to operation no trace of function can be elicited by the caloric tests. With the vertigo appear the other labyrinth signs. The period of irritation may be so brief that the typical nystagmus to the affected side with falling and pointing to the sound side are lost in a violent nystagmus in both directions and total incapacity to stand or even sit upright. This stage is quickly succeeded by the signs of complete destruction, total loss of labyrinthine function, cochlear and vestibular, on the affected side, with labyrinthine signs from the sound labyrinth.

When compensation is reached nystagmus, falling and pointing cease, the caloric test is negative but the rotation tests are normal. This normality of rotation tests with a dead labyrinth (Ruttin's reaction) must be due to some change in the healthy labyrinth which alters the normal relations of ampulli-petal and ampulli-fugal currents in the canals and makes the stimulus equal in either direction.

SOME GENERAL PRINCIPLES

Details of the operative technique are not germane to the present discussion, but we may consider some general principles.

In the first place, in the suppurative labyrinthitis the aim of surgery is not to alleviate the vertigo, but to ensure against meningitis. It will now be generally admitted that, in the first enthusiasm for labyrinthine surgery far too many labyrinth operations were done, and sometimes ill-judged operations precipitated the very disaster which the surgeon hoped to prevent. On the other hand many of us believe that the reaction has now gone too far; the belief that no labyrinth operation should be done until meningeal signs appear is responsible for dangerous delays. No meningeal signs can be found until the meninges are irritated, and in the most dangerous infections massive invasion precedes irritation.

On this basis it is possible to formulate some general rules.

1. So long as the labyrinth preserves any function it is unlikely that infection of the cavity has taken place.

2. When the labyrinth is destroyed in the presence of a middle ear infection, it is legitimate to assume that the labyrinth is itself infected.

3. When the cavity of the labyrinth is infected, and not till then, the meninges are in danger.

On these rules our treatment will be as follows:—

1. In circumscribed labyrinthitis the labyrinth cavity is unaffected. A mastoid operation, either partial or complete, must be done so as to expose the diseased area of the labyrinth wall. The diseased area must not be interfered with in any way. No labyrinth operation must be done. The only exception is in the rare cases where the erosion does not heal, although the rest of the mastoid cavity does, and incapacitating vertigo persists. In this condition it may be necessary to destroy the labyrinth in order to relieve the patient. The best way of doing this is by injection of alcohol into the labyrinth through the fistula. The operation, although simple, is not devoid of risk, and must only be undertaken as a last resort.

2. In serous labyrinthitis the defences are obviously adequate. Unless signs of a suppurative invasion appear no operation of any sort should be done until all the signs of the attack have passed off. Then a radical mastoid should be performed.

a right angle to the handle, and covered with rubber. With this instrument the skin of the face is plucked and stroked in various ways, sufficiently explained by the terms " massage-expression," " massage-pincement," and " massage-flagellation." The author claims that this instrument is the modern representative of the ancient strigil, which, as classical scholars will remember, was employed by the athletes and ladies of Rome for keeping the skin in good condition. The author's rubber-covered forceps may also be used as a means of producing local anaesthesia, for if a piece of the skin be grasped between the blades and held there for a few minutes it will become sufficiently numb for minor operations. Naturally the chapters on *x* rays and radium form an important portion of the book, and Dr. Acquaviva's remarks on these important subjects are informed both with a modern outlook and with sound common sense. In the treatment of hypertrichosis, the bane of both practitioner and patient, he prefers diathermy to electrolysis ; and, due precautions being observed, is not unfavourably disposed to the employment of an ointment containing thallium. This book is certainly worth the attention of all those who are interested in the treatment of cutaneous blemishes ; they will probably glean some valuable hints from it. The illustrations and diagrams are clear and useful.

Dr. A. BOUTELIER has written a very readable account of the commoner cutaneous diseases to which infancy is liable,[5] and very properly the longest chapter of all is that which deals with eczema. He treats of it in three parts: eczema in babyhood, in the " second infancy " (by which he means children between the ages of 2 and 8 years), and in the " third infancy " (or over the age of 8)—but at this age the disease does not differ in any important particular from the forms in which it is found in the adult. In the much-discussed subject of the etiology of eczema the author does not take us very far, although he attaches importance to visceral troubles, endocrine disturbances, milk diet, and cutaneous sensitiveness. Elaborate directions for treatment are given, prefaced by warnings of what not to do. For the most part we cordially agree with the prohibitions given, but it is difficult to understand the suggestion that the little patients should not be admitted to hospital for fear of exposing them to a rapidly fatal septicaemia. In our experience this is a groundless apprehension, and in-patient treatment is often the only hope of securing amelioration in a severe case. Nor is it very necessary to warn against curing eczema too quickly for fear of resulting complications ; the difficulty, rather, is to cure it at all, even slowly. We are aware that sudden death in infantile eczema is traditional, and that it is supposed to follow the sudden disappearance of the eruption ; but it is certainly very rare. Remaining sceptical, we prefer the view that what really happens is that as the circulation fails the erythema fades away. But, in general, there is little to find fault with in Dr. Boutelier's description of the dermatoses of infancy and in the directions given for their treatment. The illustrations—for the most part photographs of cases—are good and well reproduced. We need hardly say that there is no index ; there never is in French medical books.

Since the introduction of carbon dioxide snow some twenty-five years ago, cryotherapy has been practised with more or less enthusiasm by most dermatologists. Within the first few years of its employment it was used for the most diverse forms of skin disease, including lupus erythematosus, epithelioma, acne, lichenification, etc. At the present time its use is confined by most practitioners to the treatment of superficial venous naevi and warts, and within these limitations it gives very good results. Dr. LORTAT-JACOB has always been a keen cryotherapeutist ; and those who desire an authoritative account of the whole subject, and wish to know to what diverse ends the pencil of carbon dioxide snow may be applied, will find his treatise[6] on the subject very interesting. There is scarcely any form of dermatosis which cannot be ameliorated, if not cured, by solid carbon dioxide. Even the nodules of leprosy may be diminished by its application, although it is only fair to state that Dr. Lortat-Jacob does not claim the striking results described by a Polish writer, who states that not only do the nodules actually treated disappear, but also others which have been left untouched. This authority thinks that the frozen nodules provide a kind of vaccine which has far-reaching effects. Dr. Lortat-Jacob has also devised a useful apparatus for the application of CO_2 snow, by means of which the area of treatment may be limited to any required dimensions. The technique is explained in this volume.

ANOMALIES OF THE COLON

Le Dolichocolon,[7] by Drs. CHIRAY, LOMON, and WAHL, presents a point of view. Historically, the first evidence of variations in the size and position of the large bowel came from the anatomists and morbid anatomists. Next, the surgeons, working on volvulus and on the effects of chronic intestinal stasis, drew attention to the pathological part played by elongation of segments of the colon. With the introduction of *x*-ray observation of the colon, particularly when filled by an opaque enema, further light was thrown on the frequency of enlarged and elongated portions of the large intestine. Dr. Chiray and his collaborators point out that these variations and their pathological consequences are far from being recognized by the medical profession even to-day. The book is an attempt to define a syndrome which has as its anatomical basis an elongation of the colon, and is built on an analysis of the symptoms and associated conditions in a series of cases in which *x*-ray examination had shown an elongation of one portion or the whole of the colon to be present. The authors differentiate an acquired form characterized by elongation of the whole or some segment of the colon, which they therefore name " dolichocolon," from the megacolon of Hirschsprung's disease, which is a congenital abnormality.

In the causation of dolichocolon chronic constipation is of prime importance. The onset is often insidious, and the condition is not usually established till adult life is reached. When established, a triad of symptoms commonly occurs—constipation, excessive gas in the colon, and crises of abdominal pain. The constipation may be spasmodic, and does not yield to laxatives, or even energetic purgation. The excessive gas is not necessarily related to increased fermentation or putrefaction of bowel contents, but seems rather to be due to stasis and defective elimination of gas. The abdominal pain associated with dolichocolon varies in character, but is not related to food ; it is often exaggerated by walking or riding in a car, and in certain postures. It may be little more than discomfort, or severe and colicky, with nausea and even vomiting, as in a partial obstruction. Secondary symptoms may occur—dyspepsia, palpitation, sense of incomplete evacuation of the bowel, and even colitis, though the condition may persist for a long time without evidence of colitis. In the later stages the patient loses weight, is febrile, and may be icteric.

[5] *Quelques Dermatoses Communes de l'Enfance*. Par Dr. A. Boutelier. Paris: Gauthier-Villars et Cie. 1930. (Pp. 231 ; 28 figures. 30 fr.)

[6] *La Cryothérapie*. Par L. Lortat-Jacob et G. Solente. Paris: Masson et Cie. 1930. (Pp. 246 ; 38 figures. 35 fr.)

[7] *Le Dolichocolon*. Par M. Chiray, A. Lomon, R. Wahl. Paris: Masson et Cie. 1931. (Pp. 209 ; 44 figures, 26 radiographs. 40 fr.)

The authors have analysed twenty-eight cases in which a dolichocolon was demonstrated by *x* rays after an opaque enema, and illustrate their thesis with some excellent reproductions of radiograms showing redundancy of the whole or of parts of the colon. In the literature anything from 4 to 10 per cent. of cases examined with opaque enema show redundancy of the whole or of some segments of the colon, and the discovery of this condition does not necessarily lead to a useful result. Moreover, the treatment advocated by the authors—purgation and enemata—does not alter the anatomical condition, and so cannot be expected to improve the patient's health. The case records and illustrations are good, but the book is worth reading rather than studying.

INTERPRETATION OF BLOOD EXAMINATIONS

The making of haematological books is becoming almost a nuisance. Unfortunately the compilation habit is too easily acquired. *The Clinical Interpretation of Blood Examinations*,[8] by R. A. KILDUFFE, is compiled chiefly from American medical and scientific journals, and is intended to appeal to readers in and about Atlantic City. There are some sections which are not conceivably useful to any physician, but the greater part of the book will be read with interest and profit, especially those chapters dealing with the estimation of haemoglobin, with blood groups and transfusion, the classification and description of white cells, and the diagnostic and prognostic values of leucocytosis and leucopenia. The account of sedimentation tests seems disproportionally extended, and will be of doubtful interest to the busy physician. The serological tests for malignancy are of more historical than practical value, serving only to increase the size and weight of the volume. The text suffers from repetition, though that may perhaps help to underline rather than delay reading. This book is among the best examples of its class, and contains within one binding much sound information for those who have time for study.

SURGERY FOR NURSES

The small book of some four hundred pages, on *Surgical Nursing*,[9] by Dr. HUGH CABOT of the Mayo Clinic and Professor MARY DODD GILES of Vanderbilt University, will interest many practitioners as well as the nurses for whose instruction it is primarily intended. It is impossible in writing a book of this sort to draw a hard line between knowledge necessary for nurses and such knowledge as is purely surgical and to be found in the textbooks. Dr. Cabot has wisely allowed himself to roam in the fields of pure surgery in many parts of the book. These excursions render it all the more interesting to nurses and instructive to surgeons, who should profit by many hints on practical treatment of surgical conditions. Erysipelas is a disease of more importance in the United States than in this country, if we may judge by the space devoted to its treatment and nursing in this book. The instructions for the nursing of patients suffering from trigeminal neuralgia, before and after operation on the Gasserian ganglion, strike us as particularly useful. We cannot say as much for the part on fracture of the neck of the femur, in which the danger of hypostatic pneumonia is not dwelt on, as it is in the paragraphs on nursing after prostatectomy. The remarks on the necessity for early use of the catheter before distension comes on, after various injuries and operations in the pelvic neighbourhood, are evidently the outcome of experience and sound judgement, and should be taken to heart. Fractures are dealt with somewhat cursorily.

[9] *Surgical Nursing.* By Hugh Cabot, M.D., C.M.G., F.A.C.S., and Mary Dodd Giles, B.S., R.N. Philadelphia and London: W. B. Saunders Company. 1931. (Pp. 428; 123 figures. 14s. net.)

NOTES ON BOOKS

The demand for a fifth edition of *Clinical Electrocardiography*,[10] by Sir THOMAS LEWIS, little more than two years after the fourth, proves the continuing usefulness and popularity of this manual. No attempt is made to deal with academic problems or experimental work, the contents being limited to those electrocardiographic abnormalities which are likely to be met in clinical medicine. This electrical method of investigating rhythm and myocardial function has not reached the dead end that some would have us believe. The fourth edition was enlarged by the inclusion of a section on the electrocardiographic changes in coronary thrombosis, and the present volume shows a very different outlook upon bundle-branch lesions and premature beats than did the third. As Sir Thomas Lewis remarks in reference to the principal types of bundle-branch block, "which of these two types represents the human levogram and which the dextrogram has recently developed into a matter of debate." The trend of opinion, especially in the United States, forecasts a revolution in our interpretation of these and other electrocardiographic abnormalities. There seems little doubt that further editions of *Clinical Electrocardiography* will be demanded within the next few years. The lucid and precise exposition of future advances by Sir Thomas Lewis will be eagerly awaited by all clinicians.

The second edition of his work on sexual diseases,[11] by Professor ROBERT OTTO STEIN of Vienna, who was for many years assistant to Professor Finger in Vienna and Professor Jadassohn in Berlin, has been brought up to date by inclusion of the acquisitions to our knowledge since the first edition in 1921. The book therefore contains a description of lymphogranulomatosis inguinalis, the recent additions to the therapeutics of syphilis such as myosalvarsan and preparations of bismuth, and of new methods for diagnosing and treating gonorrhoea. Condyloma acuminatum, herpes genitalis, pseudo-syphilis, and ulcus vulvae acutum are discussed in the appendix. The text is liberally interspersed with coloured plates of wax models from the clinics of Professors Finger, Pirquet, and Knoepfelmacher at Vienna.

Sir JAMES CRICHTON-BROWNE, with his wonderful vitality, has followed up his popular "What the Doctor Thought," published a year ago, by *The Doctor's Second Thoughts*,[12] which date back at least as far as 1862, when the author was in Paris and collected some stories about Piorry's supreme faith in the diagnostic powers of his pleximeter. The numerous readers who know Sir James as the prince of after-dinner speakers will naturally expect a wealth of good stories in these recollections of Victorian, Edwardian, and Georgian times, and they will not be disappointed. Speaking at a dinner in London, he remarked that there was a specialty for every organ in the body except perhaps the umbilicus, whereupon Sir Samuel Wilks whispered to him, "You forget the Royal Naval Hospital." There are many interesting recollections of the men and manners of the past, and thus, though the first person singular is little in evidence, it is not difficult to get an idea of the veteran author's many-sided interests and friends.

In a handy little volume, entitled *The Medical Evidence before the Royal Commission on Licensing, 1930*,[13] Dr. COURTENAY C. WEEKS has ably summarized in seven chapters the medical evidence presented by sixteen medical witnesses from the various standpoints of history, social hygiene, physiology, psychiatry, therapeutics, legislation, and embryology.

THE TRAINING OF THE OBSTETRIC SPECIALIST

In contemplating the establishment of a National Maternity Service it is generally recognized that this must be built upon the threefold foundation of general practitioners, midwives (or nurse-midwives), and obstetric specialists. A great deal of consideration has been given to the provision of general practitioners and midwives, especially to their original training as students and to their subsequent periodic re-education when in practice. It is time to face the question "How are the obstetric specialists to be provided?" Unless they are available, in large enough numbers and fully equipped for their work, the National Maternity Service will not yield the results which are expected of it. That obstetric specialists, adequately trained and in sufficient numbers, exist at the present time must not for a moment be assumed. Where are they to come from? It will probably be admitted by all who have given consideration to the matter that, generally speaking, the men who become consulting physicians, or surgeons, or specialists in this country are not, in fact, trained for their most responsible work except in a certain desultory and haphazard manner. The acquisition of certain diplomas, it is true, is regarded as essential; beyond this the requirements are almost entirely unspecified, and in so far as practical training is concerned there are no accepted standards. So little has practical training been valued in the past that it has on occasions happened that a great medical school has appointed to its staff a brilliant man who was, in fact, almost entirely inexperienced in the work of the department placed under his care. It is even conceivable that a university chair in midwifery might be filled by one who had never held a resident hospital appointment as an obstetric officer.

In midwifery the need for the intensive practical education of medical students has been repeatedly emphasized; it is even more important that the men who teach them should themselves have been adequately trained and taught. In a recent address by Professor Whitridge Williams of Johns Hopkins University the opinion has been expressed that it requires "four or more years of hospital residence to make a thoroughly competent practical obstetrician."[1] Even if this should be regarded as a hard saying it cannot be disputed that midwifery, in a peculiar degree, is a subject which can be learned only by assiduous devotion to the routine of hospital work, where alone familiarity can be acquired with the unforeseen emergencies and the rapid alternations from normal to abnormal, which form the salient features of obstetric practice. There are very few, if any, obstetric teachers, either in this country or in the United States, whose training before appointment had reached the standard suggested by Whitridge Williams. There are very few lying-in institutions in Great Britain and Ireland where one person can remain in residence as junior graduate for more than twelve months; the annual number of men who can receive even this extent of practical training is therefore strictly limited. The great bulk of the men and women to whom is committed the nationally important task of educating medical students in midwifery start with an inadequate practical equipment, and must strive to make themselves efficient as they proceed with their task. The perfunctory methods which have been tolerated heretofore will not suffice in the new era which is opening up before us. The bad training in midwifery of our students in the past has not been entirely due to the lack of bedside facilities; the shortcomings of the teachers and of the methods they have employed have played a part, probably an important part, in our inability to produce skilful obstetric practitioners, and in the consequent national failure to lower the maternal mortality rate. It is coming to be recognized that a lying-in institution requires continuous service, not only from the junior members of its staff, which it enjoys at present, but also from the senior members of long and wide experience. Under prevailing conditions it often cannot command the services of its senior members at the times when they are most urgently needed. Only when this grave defect in organization has been remedied will our lying-in institutions be able to measure themselves beside the great obstetric clinics of the Continent.

Apart from the obstetric teachers, a second class of junior obstetric specialists is required to work a National Maternity Service. These will be men in general practice who by training and by practical work have fitted themselves for the duty of acting as local consultants. Such men will naturally endeavour to secure one of the diplomas in midwifery which have recently been established. They must acquire their special practical training after graduation; but how and where is it to be obtained? Facilities for post-graduate instruction in midwifery are practically non-existent in this country at the present time, but it is assumed that a beginning will shortly be made by the projected British Post-Graduate Hospital and School. Generally speaking, the now existing opportunities for clinical teaching of midwifery are barely sufficient to meet the needs of training for medical students and pupil midwives. The provision of the additional facilities for post-graduate education which are now so urgently needed is a necessary preliminary to the launching of a National Maternity Service, and the generous allocation made for the Post-Graduate Medical School by the present Minister of Health shows that the Government is aware that the duty of making provision for post-graduate training is one which the nation itself must share with the medical profession and the voluntary hospitals.

These matters all have a direct bearing upon the problem of maternal mortality; to overlook them will be to envisage the problem incompletely, and to jeopardize the full success of a National Maternity Service when the time comes to put it into operation.

THE PROBLEM OF SUICIDE

The discussion on suicide at the Annual Meeting of the British Medical Association at Eastbourne has focused attention upon an important problem of everyday life. The social, forensic, and psychological aspects were mainly considered, as will be seen from the three opening papers published this week. Suicide is a many-sided topic, and lack of time doubtless forbade more than brief allusion to the cultural, ethical, and religious, and even the more truly medical and psychiatric points of view. Suicide we have always with us: the average number of successful suicides in England and Wales now reaches some 5,000 a year, or about 14 suicidal deaths every twenty-four hours. This figure usually causes great surprise to those who hear it for the first time. And the vast majority of the suicides are not in any ordinary sense of the word insane, *pace* Sir Hubert Bond—unless the act of suicide itself defines insanity, which by the present law, as Dr. East showed in his paper, it clearly does not. It is worth remarking in this connexion that only about 50 of the annual total of successful suicides occur in the certified insane. While 5,000 cases per annum is an alarming number, it is important to have Sir Hubert Bond's demonstration that, except possibly in the year 1930, there has been no substantial increase in the number of suicidal deaths in this country. The experience of other countries, such as Germany, warns us, however, to expect an increase in times of extreme financial depression, such as the present. On the other hand, the number of attempted suicides reported to the police in England and Wales has risen considerably in recent years, and it is quite certain that the number so reported is far short of the real total.

The discussion will have served a very useful purpose if it draws the attention of the medical and legal professions to three or four main points: the state of the law in the matter, and the mode of execution of the relevant statutes; the absence of any systematic provision for the care and treatment of those who attempt to take their own lives; and the need for technical investigation, along psychological and social lines, of the causes of suicide, attempted or accomplished. The last point was illustrated by the paper of Dr. Crichton-Miller on the psychology of suicide, which is not only of interest in itself, but stimulates the reader to an awareness of the need for exact and individual research on this point. It is a curious fact that such a humane field of research on a contemporary problem should have been so neglected as to make it impossible to find a comprehensive book on the subject written in this country for many years past. Research is not, however, an essential preliminary to the devising of more satisfactory methods than exist at present for dealing with the person who has attempted suicide. Magistrates, police court missionaries, and hospital chaplains do nobly and well in this matter; but there is no definite organization, and as a rule there is no recognition of the fact that a medical man with special training in mental aberrations of all degrees, aided by a psychiatric social worker, would be a highly useful link in a co-operative advisory chain for the rehabilitation and future stabilization of the person who has attempted suicide. Psychiatrists believe that they have a definite social contribution to make in this way, if the chance were more often afforded.

Steps in this direction would be facilitated by a change in the legal attitude; although again the latter—such is the wisely elastic practice of the law—is not a necessary preliminary. Nevertheless, the law regarding suicide is productive of various anomalies, some of them more hurtful than advantageous. It is a familiar paradox, but worth propounding again, that if a man succeeds in committing suicide he is nearly always declared insane, and therefore irresponsible; whereas, if he fails he is nearly always considered responsible, and is liable to imprisonment. It is true that imprisonment is now used, as Dr. East showed, in a kindly and protective way, but it is illogical nevertheless; and there is very little doubt that a period of sojourn in a mental hospital would be far the more beneficial procedure, for although most persons who have attempted suicide are by all ordinary criteria sane, they do as a rule suffer, as Sir Hubert Bond pointed out, from some kind of mental disorder. It is true, also, that some contend that the purpose of the law in treating successful suicide as a felony is to deter prospective suicides from their fatal act; but this is surely a psychological absurdity. If religious scruples are absent (and it is interesting that the suicide rate tends to be lowest in Roman Catholic countries and districts) then a legal deterrent is not likely to avail against an act committed as a rule only in the extremes of personal adversity, real or imagined. Again, when a suicide has been successful, it is not unequivocally comforting to the relatives (except from the insurance point of view), nor does it always represent the actual truth, that a verdict of "suicide while temporarily insane" should be returned. But in the present state of the law of England, which regards the act as a crime in a sane person, and demands in every instance a coroner's inquest, any other verdict is in most cases necessarily more unkind. In all these matters the debate at Eastbourne calls attention to the need for reconsideration and reform.

CLINICAL TRIALS OF NEW REMEDIES

The Medical Research Council announces that it has appointed a Therapeutic Trials Committee to advise and assist it in arranging for properly controlled clinical tests of new products that seem likely, on experimental grounds, to have value in the treatment of disease. The members of the committee are: Professor T. R. Elliott, F.R.S., physician to University College Hospital (chairman); Sir E. Farquhar Buzzard Bt., Regius Professor of Medicine, University of Oxford; Dr. H. H. Dale, Sec.R.S., Director of the National Institute for Medical Research; Lord Dawson of Penn, President of the Royal College of Physicians of London; Professor A. W. M. Ellis, physician to the London Hospital; Professor Francis R. Fraser, physician to St. Bartholomew's Hospital; Sir John Parsons, F.R.S.,

ophthalmic surgeon to University College Hospital ; Dr. J. A. Ryle, physician to Guy's Hospital ; Sir John Thomson-Walker, consultant urologist to King's College Hospital ; Mr. Wilfred Trotter, F.R.S., surgeon to University College Hospital ; and Professor D. P. D. Wilkie, surgeon to the Royal Infirmary, Edinburgh. The secretary is Dr. F. H. K. Green. Conditions have been the subject of discussion and agreement between the Medical Research Council and the Association of British Chemical Manufacturers, under which the Therapeutic Trials Committee will be prepared to consider applications by commercial firms for the examination of new products, submitted with the available experimental evidence of their value, and will arrange appropriate clinical trials in suitable cases. The committee will work in close touch also with the existing Chemotherapy Committee, which is engaged for the Medical Research Council in promoting researches aimed at the discovery and production of new remedies. The Therapeutic Trials Committee will invite suitable experts in particular branches of medicine or surgery to undertake the clinical tests of preparations accepted for trial. The reports upon the results will be published under the authority of the committee. We welcome this announcement, on behalf of the profession generally. Machinery for securing an impartial and authoritative verdict on new remedies has long been an urgent need.

THE NATIONAL ECONOMY REPORT

The report of the Committee on National Expenditure was issued on July 31st as a Blue Book.[1] Five of the seven members recommend drastic economies which, if adopted by Parliament, would effect a total cut of more than £96,500,000. Of this sum £66,500,000 would be saved out of the cost of unemployment insurance, £13,600,000 out of the education estimates (mainly in respect of teachers' salaries), and £7,865,000 out of the Road Fund. These are large figures ; but the number of persons concerned is in each instance correspondingly large. Other retrenchments include £2,599,000 on the pay of the Defence Services of the Crown (including the medical branches), £1,000,000 under National Health Insurance, and postponement of an Exchequer grant of £1,500,000 for the development of a National Maternity Service. Everyone knows that sacrifices all round are needed to cope with a national emergency, and everyone knows that most of the sectional interests affected will resist an attack on the standard of life of their members. The Minority Report agrees to the proposed cuts in the pay and pensions of the fighting forces, and to the cut of a shilling in the capitation fee of insurance medical practitioners, but it dissents from the recommendations in respect of unemployment insurance and from the suggestion to withhold an annual State grant for extension of maternity services. The Cabinet has appointed a subcommittee of five to consider these reports during the parliamentary recess, and the Chancellor of the Exchequer is expected to make a statement to the House of Commons when it reassembles. In the meanwhile, political parties and organized bodies representing the interests concerned will no doubt have something to say. Beyond observing that the medical profession has never been behindhand in putting the public interest before its own, we refrain from comment at this stage, and will merely quote para. 409 of the Majority Report, which appears to express the opinion of all the members of the Committee on National Expenditure:

"We are . . . of the opinion that the payments to the doctors are too high in present circumstances. These consist of a flat capitation allowance of 9s. per annum for every insured person in a doctor's list, in addition to mileage allowances in rural areas, amounting, in the aggregate, to £250,000, and equivalent on the average over the whole of the medical panels to about 4½d. per insured person. It is common knowledge that the standard of remuneration of the medical profession has been greatly increased as a result of the Health Insurance Scheme, and there has been growing difficulty in filling salaried medical posts under the Government and the local authorities at rates of pay corresponding to those in other classes of public service. In present circumstances we should not regard a reduction of the capitation rate to 8s. as unreasonable. This would represent a saving to the scheme of about £750,000, and enable it to meet the cost of central administration to this additional amount."

[1] Cmd. 3920. London: H.M. Stationery Office. 1931. (4s. net.)

CHOLESTEROL IN MENTAL DISORDERS

Attention has been directed in recent years to the possible relationship of changes in cellular metabolism to morbid processes, such, for example, as malignant disease. In the case of mental disorders such a factor cannot be lightly disregarded in view of the enormous amount of oxygen consumed by the brain of a waking animal—namely, 360 mg. per minute, as compared with 4 mg. by the skeletal muscles, and 28 mg. by the salivary glands. In the brain, moreover, there is present a very large percentage of phospholipins, substances intimately associated with the activation of vital processes, and the cerebral cholesterol content is in great excess as compared with that of other tissues. In view of these facts Dr. B. H. Shaw, medical superintendent of the Staffordshire County Mental Hospital, in collaboration with Dr. J. S. Sharpe, has investigated the significance of cholesterol and lecithin in metabolism.[1] Among the facts demonstrated was an inhibiting influence of cholesterol on haemolysis, and its activation by lecithin ; also the presence of a thermolabile ferment in the serum, which activated haemolysis, and which appeared to vary directly with the blood cholesterol content. Cholesterol was shown to be an influential controlling factor in oxidation processes, its power being best exercised in relation to lecithin when the relative amounts of these two substances were those normally present in blood. Lecithin was also shown to have a power of attracting potassium ions, and the presence of cholesterol in the cell membrane definitely retarded the diffusion of this metal. In certain states of mania, hypercholesterinaemia was demonstrated, bringing about anoxaemia of the tissue cells, though with relatively less destructive effect on the neurons, since ferment action was also inhibited. The brains of general paralytics were found to be remarkably deficient in cholesterol, and the authors suggest that some deficiency of this kind may in certain cases of syphilis have a bearing on the initiating of infection of the central nervous system. In contrast with the manic states, the blood cholesterol content in dementia praecox is greatly diminished. As regards treatment in such cases

[1] *Journal of Mental Science*, January, 1931.

of cholesterol deficiency, the obvious indication is to restore the normal blood cholesterol as quickly as possible and before the neuron is irretrievably damaged. In pyretotherapy the increased body temperature tends to mobilize the cholesterol, increasing it temporarily in colloid form in the body fluids. A high protein diet was found to have no effect in stimulating metabolism in dementia praecox, and in such cases the authors are endeavouring to increase the cholesterol blood content directly by parenteral injections of this substance dissolved in olive oil, and also by feeding with cholesterol emulsions and colloids. They report the case of a woman, aged 25, suffering from dementia praecox. On admission her blood cholesterol content was 0.03 gram per cent. Parenteral injections of 0.25 gram cholesterol in olive oil were given every third day, and a special diet was devised with a view to promoting cholesterol production. After a month she was given by the mouth daily doses of half a gram of cholesterol in emulsion, and this treatment was continued for a further two months. Steady and continuous mental improvement ensued, with synchronous increase of the blood cholesterol, which regained the normal figure at the end of three months. She then appeared to have recovered completely, and has remained well since. The etiological interest of this research is undeniable, and it gives further support for the more careful consideration of possible biochemical factors in mental disorders.

PREVALENCE OF POST-VACCINAL ENCEPHALITIS

According to the minutes of the last session of the Permanent Committee of the Office International d'Hygiène Publique, held in Paris in May,[1] post-vaccinal encephalitis seems to be definitely on the decrease in Great Britain, Germany, and Holland. Only a few cases have occurred in Great Britain since the summer of 1930. In Germany, where each case notified is seen by a neurologist, and then examined by a special commission, 9 cases and 1 doubtful case were verified in 1930, against 20 and 22 in the two preceding years, 2 to 2½ million vaccinations having been done annually. In Holland no fresh case has occurred since May, 1930, although about 25,000 vaccinations have been done. From 1924 to 1931 the average was 1 case among 4,695 vaccinations, and 1 death among 16,000 vaccinations, but among children under 2 years of age the proportion was only 1 case to every 25,000 vaccinations. As in England, primary vaccinations of children at school age, which are obviously the most dangerous, are much less frequent than formerly. In the United States very few cases were known before 1928; in the last three years there have been 40, of which 18 were in 1930. Five of these cases occurred simultaneously in a town among children about 6 years of age, vaccinated by means of one insertion only. One case was notified at Stamboul in Turkey out of 1,000 vaccinations. Thirty cases of encephalitic syndromes following various infectious diseases were notified in Great Britain in 1930. Seventeen cases of acute disseminated encephalomyelitis occurred spontaneously in Poland, in which the anatomo-pathological lesions are said to be the same as those of post-vaccinal encephalitis.

SOUTH LONDON

An exceptionally interesting and valuable survey of social conditions and activities in the poorer parts of London will be found in a small volume by the Bishop of Southwark entitled, *In the Heart of South London*.[1] It is valuable because it contains the results of direct and unbiased observations by one who is exceptionally fitted by knowledge and experience to observe truly, to infer correctly, and to suggest wisely. It is interesting because of its straightforward, smooth, and attractive style, and of its pervasive human sympathy and spiritual appeal. The purpose of the book is to give some account of the social conditions in South London, with special regard to the evil effects of overcrowding on the health and happiness of those who live there. South London for this purpose means the district on or near to the right bank of the Thames from Wandsworth to Woolwich. The individual instances given are all taken from that district, and this is true also of the actual social agencies described; but of course the general description of the conditions of life and conduct, and the problems arising out of these, apply to corresponding parts of other metropolitan districts, and, indeed, to many provincial towns. The book, therefore, should make a wide appeal. Dr. Garbett fully and gratefully acknowledges all that has been done towards the amelioration of distress and the betterment of social evils by communal, municipal, religious, and private agencies. He specially mentions in more than one place the work of the medical officers of health. In spite of a really remarkable improvement, however, it is evident that appalling conditions still prevail in many districts, and that these affect many thousands of human lives in a way devastating both to health and to morals. The Bishop of Southwark tells of these effects, in successive chapters, on the children, the adolescents, the adults, and he shows that in all cases the root of the matter is in overcrowding, and the solution in dealing suitably with the housing problem. His chapters on this subject are powerful, sane, reasonable, and full of sensible and practicable suggestions. The book gives a wide and true, but of course not exhaustive, survey of its subject. It is to be hoped that it will be widely read, and that it will be a means of stimulating the social sympathy, personal interest, and financial help which are so much needed.

WOAD

The only association of this word in the minds of most people is with the ancient Britons, as described by Caesar in his Commentaries, where he tells us that they painted themselves blue with woad in order to appear more horrible in fight. Those, however, who have read *The Woad Plant and its Dye*,[2] by the late Dr. Jamieson B. Hurry, must realize that the product of the woad plant, or *Isatis tinctoria*, was for hundreds of years of the greatest commercial importance. The dye prepared from it was almost the only blue used for colouring cloth, until it was displaced by the oriental indigo. Whole districts of France and Germany were enriched by its culture, and in Italy and England the

plant was widely grown until the beginning of the nineteenth century. How the Britons and Picts came to know that this yellow-flowered member of the great order of Cruciferae could be made to provide a blue pigment is a mystery. Probably they did not prepare woad themselves, but obtained the pigment ready for use from the Continent. It was only by a process of fermentation of the powdered leaves that the blue dye was obtained.

> "Anything green that grew out of the mould
> Was an excellent herb to our fathers of old,"

and woad was no exception to this rule. It is to be found, judging from the wealth of quotations given by Dr. Hurry, in almost every herbal or pharmacopoeia until the eighteenth century, when James, in his medical dictionary published in 1745, wrote:

"Woad is restringent [that is, astringent] and drying and sometimes us'd to stop both inward and outward bleedings. It is, also, applied with good success, for Ruptures and Strains and to strengthen the Joints. It is an ingredient in the Emplastrum ad Herniam. It is esteemed an excellent vulnerary."

Nowadays, whether as a medicament or a dye-stuff, woad is obsolete, but Dr. Hurry, with great erudition and almost incredible industry, has rescued it from mere oblivion in this book, into which we think he has put all that is known or can now be known of the history of the plant, the methods of preparing the dye, the laws which in sundry lands regulated its sale and use, and the taxes and customs which were levied upon it. We deeply regret that the author's death, at the beginning of last year, sets *finis* to the list of his works on medical subjects, and on the history and archaeology of Reading, which he loved so well.

INFANT MORTALITY IN SOUTH AMERICA

Following a conference held at Montevideo in 1927, inquiries have been made into the causation and prevention of infant mortality in certain parts of South America. The results obtained were discussed at a second conference held at Lima last year, and now form the subject of a League of Nations Report by Professors R. Debré and O. E. W. Olsen.[1] Urban and rural districts in the Argentine Republic, Brazil, Chile, and Uruguay were investigated, and the data obtained carefully analysed, each report being fully discussed in order to throw light on the problems peculiar to each country. The results of European inquiries were also before the conference as a sort of background, although direct comparisons were not attempted. Statistics, economics, ethnology, and the medical causes of infant mortality were the main subjects discussed. Statistical returns were unsatisfactory for various reasons, including the fact that in certain districts the practice of secret burial still exists. Social and ethnical considerations were complicated by the question of illegitimacy, the number of illegitimate children being very high in the poorer quarters. Many couples live together without contracting legal marriage, and, in some districts, they are even more numerous than those legally married. Children in such homes, though illegitimate, are brought up under much better conditions than the children of prostitutes, and this has to be borne in mind in making deductions. Housing and climatic conditions deserve further study, but undoubtedly the most serious factors affecting infant mortality are ignorance and a low level of education, as will be seen when the principal medical causes of death are reviewed. The three main groups of deaths are: (*a*) from digestive disorders; (*b*) from infectious diseases, including diseases of the respiratory system; and (*c*) death during the obstetrical period. The first group accounts for the highest proportion of deaths, due, undoubtedly, to the combined effects of climate, unsuitable diet, bad nursing, and an inadequate supply of good milk, while the methods and material of artificial feeding were found to be deplorable. Respiratory complications of whooping-cough and measles are common, and favoured by the climate on the Pacific coast, where very cold nights follow very hot days. The general conclusions of the conference are set out under several headings. Most stress is laid upon co-ordination between central authorities and local enterprise, whether private or public, for the provision of child welfare and maternity institutions. Various economic and legislative measures, concerned with maternity benefits in industrial areas, to encourage breast-feeding and to prevent the abandonment of the child under the pressure of poverty, are also recommended.

BOARD OF CONTROL: ADVISORY COMMITTEE

The Board of Control, with the approval of the Minister of Health, has appointed the following to advise the Board upon questions arising in connexion with scientific and ancillary mental health services: Mr. L. G. Brock (chairman), Sir Hubert Bond, M.D., Mr. Robert Bruford, Mr. W. E. Lovsey, Dr. T. S. Good, Dr. Adeline Roberts, Mr. J. C. Grime, and Professor J. Shaw Bolton, M.D., with Mr. P. Barter as secretary. The Mental Treatment Act, which came into operation on January 1st, confers upon local authorities powers to provide for out-patient treatment, and for the after-care of mental patients, and, subject to the approval of the Board of Control, to undertake or to contribute to research in regard to mental illness. The Board has appointed the Advisory Committee to assist it in the consideration of schemes of research submitted for the Board's approval, and in regard to such questions as the organization of social services in connexion with out-patient treatment and after-care, on which local authorities may seek the Board's guidance. On technical questions relating to research the Advisory Committee will have the expert advice of members of the Medical Research Council's Committee on Mental Disorders.

RECOGNITION OF DR. COX'S SERVICES

The executive committee appointed at Eastbourne on July 18th (see *British Medical Journal*, August 1st, p. 199) met on the following day, when the resolutions adopted by the general committee were considered in detail. It was decided that the appeal for subscriptions should be issued in October next, and that an account should be opened with the Tavistock Square Branch of the Westminster Bank, in the name of the honorary treasurer of the fund, Mr. N. Bishop Harman. A sub-committee was appointed to choose an artist to paint the portrait of Dr. Cox.

THE PATHOLOGICAL MUSEUM AT EASTBOURNE

The Museum Committee is to be congratulated on the excellent way in which it arranged the large number of exhibits, which consisted of about eight hundred specimens, illustrations, charts, photomicrographs, and x ray plates They were grouped as far as possible in sections corresponding to the Sections of the Annual Meeting, so that it was easy to find specimens illustrating the various papers given The instructive series in the first room was lent by the Princess Alice Memorial Hospital, Eastbourne, and the East Sussex County Mental Hospital, Hellingly Perforation of the arch of the aorta by tuberculous ulceration, a brain from a case of juvenile general paralysis of the insane, and a portion of stomach from a case of suicidal cyanide poisoning were particularly interesting On the surgical side, the collections of specimens, drawings, photomicrographs, fractional test meal charts, and *x*-ray photographs illustrating various types of carcinoma of the stomach, formed a fairly complete unit—a graphic commentary on all aspects of this disease On this side, too, there were specimens from the local hospital, among which was a carcinoma of the appendix from a girl, 14 years of age

The *x* ray photographs were especially well displayed and included a series of pyelograms illustrating the excretion and ureter catheter method, and another the recent diagnostic methods in renal affections A very clear and demonstrable collection of ventriculograms, with excellent descriptions and reasoned diagnosis, was shown An exhibition of radiograms of the chest in cases of silicosis was of general as well as of special interest, since it included specimens from patients working in eighteen different occupations, varying from asbestos workers to pearl cutters, and from gold miners to gannister workers A series of exhibits illustrating physiological changes in the sex organs of monkeys was one of the features of the obstetric and gynaecological section The injected transparencies of the mammary glands of monkeys were excellent examples of the advance made in the methods of preparing specimens for demonstration It was a pity that more information did not accompany the specimens for although it was obvious enough that the mammary glands varied in size, there was no note of the size of the monkeys from which they were obtained In this section there was also a fine assembly of mounted specimens water-colour drawings, and microscope slides illustrating endometrioma of the pelvic organs Here too, it was refreshing to find that the good old diagnosis of adenomyoma has not been entirely abandoned by all gynaecologists

The feature of the pathological collection was a series illustrating infarction of the myocardium Here there was an exceptionally good group of skiagrams showing the coronary arteries in health and disease, and with them a description of the apparatus used for injecting these vessels Similar x ray photographs of a normal and of an arterio sclerotic kidney demonstrated the wide use of this particular method Celloidin casts of coronary arteries and a series of hearts and photomicrographs showing infarcts of the myocardium and their results excited general interest Specimens showing necrosed tissue the granulation tissue reaction to this, fibrosis, aneurysm formation, and rupture with and without aneurysm of the myocardium, were also exhibited in this collection In a series of normal and diseased adrenal glands were two associated with virilism—in one there was nodular, and in the other diffuse, adrenal hyperplasia an adrenal melanoma was another rarity in this group Recent experimental work on cancer was clearly demonstrated in a small exhibit of specimens, photomicrographs, charts, formulae, and graphs Other exceptional or interesting specimens in this room were a carcinoma of duodenum, a mottled stomach from a case of melancholia, and six photomicrographs taken with the 'super microscope' In the public health section in addition to the radiograms of silicosis already referred to, there was an exhibit by the National Association for the Prevention of Tuberculosis, and a series of photographs illustrating the production and distribution of milk from non reacting cows Aneurysms of cerebral arteries formed the bulk of the exhibits in the section of neurology In the oto rhino-laryngological section were a number of dissected specimens of the temporal bone, and one showing an impacted dental plate in the upper part of the oesophagus Coloured drawings, and antique and modern ophthalmological instruments made up the greater part of the ophthalmological section The dermatological section contained numerous photographs of skin conditions, including varicose ulcers, and illustrations of the use of thalium acetate in the treatment of ringworm of the scalp This section was also distinguished by good coloured transparencies Seven groups of *x* ray photographs showing abnormalities of the upper end of the femur in childhood and their effects formed the principal exhibit in the section of orthopaedics Charts and posters were shown in sections of hydrology and medical sociology

In the past the museums of the majority of medical schools have been for the most part uninspiring collections of more or less unrelated pickled specimens, coloured poorly or not at all, suspended in round jars which distorted or exaggerated their outline Many of them were in the hospital museum for no other reason than the wish of a clinician to perpetuate his triumph or in a few cases to point the moral of his mistake Recently this state of affairs has been gradually giving place to order arrangement, and more enlightened methods of display It is in this connexion that temporary museums such as that at Eastbourne, showing the latest *methods of colour preservation mounting* and *general* arrangement, are useful The inclusion of photomicrographs photographs, *x* ray photographs, charts, and diagrams with the bottled specimens can do much to add interest and life to any collection The casts and the *x* ray photographs of the coronary arteries, the injection of mammary glands, and subsequent clearing and bulk staining were all evidence of how a little ingenuity can make obscure specimens demonstrable The specimens arranged in series, such as those of myocardial infarction, illustrated how clear an idea of a process can be obtained from such a sequence It is perhaps too much to hope that museums of the future will contain only fully labelled specimens, supported by photomicrographs, pictures, x ray plates and charts but a corner might be devoted to this kind of collection even if the major part is full of unlabelled pots used as pegs for students to guess at and over which teachers and examiners can become facetious If the museum at Eastbourne assists in raising the standard of medical museums generally it will prove to have been something much more than an interesting feature of this year's British Medical Association meeting

SECTION OF MEDICINE

Thursday, July 23rd

VARIETIES OF SECONDARY ANAEMIA AND THEIR TREATMENT

At the second meeting of the Section Dr. A. DEANE (Eastbourne) was in the chair.

Dr. L. J. WITTS, in opening the discussion, confined himself to a consideration of the clinical entity, chronic microcytic anaemia. In an analysis of 183 cases of anaemia at Guy's Hospital 26 per cent. fell into this group. This was a condition far more common in women than in men, and largely confined to the reproductive period, from 20 to 50 years of age. It was characterized by a low colour index, a negative van den Bergh reaction, with a slight degree of splenomegaly in 30 per cent. of the cases. Glossitis was present in 50 per cent., koilonychia in 25 per cent., dysphagia in 15 per cent., and achlorhydria in 81 per cent. The achlorhydria preceded the anaemia, and might be a familial characteristic; it persisted after the cure of the anaemia. The treatment was by massive dosage of iron; Blaud's pill 30 grains a day, or iron and ammonium citrate 90 to 120 grains a day, cured practically every case; the larger the dosage the more rapid the cure. Transfusions were to be used only in cases of emergency. As regards other methods of treatment that had been tried, removal of septic foci alone had only been successful in 5 per cent. of cases; liver had been of no value, and hydrochloric acid was no good as regards the anaemia, though it benefited the general condition. Relapses occurred in 50 per cent. of cases two years after treatment ceased. Lack of success in treatment was due to too small a dosage, or too short a duration of treatment. Dr. Witts gave a warning with regard to proprietary medicines; almost all of those which he had tried contained far too little iron, and were quite useless in the treatment of this condition. In giving iron by injections very large quantities were necessary, and were very painful.

Professor STANLEY DAVIDSON described a series of cases showing the effect of massive dosage of iron in cases of secondary anaemia. In addition to its use in the type of case referred to by Dr. Witts, he demonstrated its value in the preoperative treatment of cases of gastric ulcer and malignant disease. In cases where the anaemia had been treated before operation the operative risk was appreciably less. He also pointed out that the same lines could be adopted in quite young children; he had given 30 grains of reduced iron daily to children of 1 year and less with the most beneficial result. A rise in the reticulocytes was not to be expected, nor did it occur with iron treatment. With regard to simple achlorhydric anaemia, [illegible] were the returns were unsa[illegible] to the difficulty in diagnosis between including the fact that in certain [illegible]ion of all the systems of secret burial still exists. Social [illegible]isease before arriving siderations were complicated by illegitimacy, the number of illegitimate[illegible] classification of very high in the poorer quarters. Mar[illegible] their response to together without contracting legal mar[illegible] which responded some districts, they are even more numero[illegible]liopathic micro- legally married. Children in such hom[illegible]rhage, chronic illegitimate, are brought up under much bet[illegible] Dr. Vaughan tions than the [illegible]ildren of prostitutes, and thi[illegible]er haemor-

[1] League of Nations [illegible] Health Organization, No. CH.[illegible]ted with London, Allen and Unwin [illegible]. (1s.)

massive iron dosage. The treatment gave rise to no increase of pain or other untoward symptoms. (2) Secondary anaemia reacting to large doses of iron and liver. There were those due to chronic haemorrhage, starvation, deficient dietary in children, past sepsis, and carcinoma. (3) Secondary anaemias responding to vitamin C, of which anaemia due to scurvy was the outstanding example. (4) The anaemias benefited by arsenic—for example, myeloid leukaemia. (5) Those benefited by transfusion—for example, aplastic anaemia and erythroblastic anaemia. Professor HENRY MOORE (Dublin) gave further support from clinical experience to the value of massive iron treatment in the type of anaemia described by Dr. Witts. He drew attention to the association of this type of anaemia with diabetes and hyperthyroidism, and pointed out in this connexion that achlorhydria occurred with undue frequency in both these conditions. Dr. ASTLEY CLARKE (Leicester) mentioned the great value of insulin given with glucose in the extreme forms of anaemia to tide over a few days of danger. He also recorded a case of pernicious anaemia treated with dramatic success by beef-muscle incubated with human gastric juice. Dr. FREWEN MOOR (Westgate-on-Sea) spoke of the anaemias associated with high blood pressure, and asked Dr. Witts for information on the effect of ultra-violet light. In his experience this form of treatment, if it was going to be successful, always showed its effect after one or two treatments. Dr. GEORGE GRAHAM reminded the meeting that ferrous salts were much more efficacious than ferric, and advised that Blaud's pill was best given in powder. Old pills were frequently passed unchanged in the stools. Dr. E. P. POULTON gave further evidence on this point. Dr. WATERHOUSE asked for information as to the blood volume in Dr. Witts's cases. Dr. HUTCHINSON (Worthing) described the beneficial effect of iron treatment in cases of anaemia in varicose ulcer, acute eczema, and hyperpiesia. In one case, where the blood pressure had been consistently in the neighbourhood of 200, after iron treatment the pressure had come down to 140, and remained about that level. Professor MEYER RABINOWITZ (New York) spoke particularly of the anaemia associated with nephritis. In his experience it was found in acute nephritis with hydraemia, and in chronic nephritis with nitrogen retention; in the latter group the anaemia might be of the pernicious type, and responded to liver treatment. Dr. J. EASON (Edinburgh) mentioned the secondary anaemia due to syphilis, and drew attention to the frequent association of myxoedema with microcytic anaemia, and asked Dr. Witts whether, in view of the frequent association of myxoedema and achlorhydria, the hypothyroidism might not possibly be the basal factor. Dr. RUSSELL emphasized that Blaud's pills must be fresh. Dr. R. A. YOUNG spoke of the use of copper. He had given 1/8 grain of copper in a pint of water daily to one patient with success, and thought that injections of collosol copper were of some value in the secondary anaemias of malignant disease. Dr. WITTS replied to many of the questions put to him.

SECTION OF SURGERY

Thursday, July 23rd

RECENT DIAGNOSTIC METHODS IN RENAL AFFECTIONS

At a meeting of the Section of Surgery, with the President, Mr. CECIL A. JOLL, in the chair, Mr. R. OGIER WARD opened the discussion on recent advances in diagnostic methods in renal affections, with the paper printed in full last week at page 175.

Dr. E. J. H. ROTH emphasized the importance of the radiologist as a link in the clinical chain formed by the surgeon and the pathologist. He said that radiological examination combined with surgical procedures should

be carried out in a special radiological theatre, and that a special table was also essential. Photographs illustrating the new table designed for the radiological department of St. Peter's Hospital were shown. Radiograms could be taken in the erect position by means of this table, which was a combined radiological and urological couch. The modifications of technique made necessary by ascending and descending pyelography were discussed in detail. The contrast shadows cast in these procedures were necessarily of a relatively faint density, and adequate preparation of the patient was imperative.

Mr. R. J. WILLAN (Newcastle) said that intravenous pyelography was still in its infancy, and that he had not yet full confidence in its use. Renal function tests were first carried out in all cases before excretion urography was performed. The speaker had not obtained such good results with abrodil as with uroselectan, but thought that possibly he had not had photographs taken soon enough after injection. He had never seen any ill effects from pyelography or urography—only occasional flushings in patients after the use of uroselectan. He then showed a series of eight completed cases which had been investigated both by uroselectan pyelography and by excretion urography, and which had been followed by operation. They included hydronephrosis, new growth of the kidney, congenital cystic kidney, and tuberculous kidney. The usefulness of excretion urography was ably illustrated by these cases. In conclusion, he said that excretion urography was very useful in cases where urethral catheters could not be passed. Mr. KENNETH HERITAGE said that while they had not yet reached the ultimate in the employment of excretion urography, from its use had crystallized out several conditions where it is of paramount value. In renal tuberculosis, hydronephrosis, and ureteric obstruction this was the case. Previous speakers had shown a very excellent and instructive series of urograms well illustrating positive findings. He would like to mention the importance of recognizing and assessing negative findings. It had frequently been said that a normal kidney might on occasion inexplicably fail to give any excretion shadow on a series of radiograms. To explain this it had been suggested that the kidneys might work alternately. Other more bizarre explanations had been put forward. If, however, it was a fact that a normal kidney might give no shadow, then, as Professor von Lichtenberg had said, the very foundations of excretion pyelography were shaken. But this was not so. In his experience, in every case in which no shadow had been seen, there had been ample explanation of this fact later, and one had often wondered at the tenacity with which a diseased kidney continued to secrete the drug. This was no doubt due to glomerular activity. Faulty preparation and technique might explain many apparent negative results. He regarded preliminary fluid restriction as important, and always took an early film five minutes after the injection, under light abdominal compression with the Potter-Bucky belt. The value of excretion urography in renal tuberculosis was well instanced by several cases. Mr. J. F. DOBSON said that at first he was disappointed at the absence of clearness in the outline of the shadow produced by uroselectan, but later appreciated the extreme value of this method. Excretion urography did not supplant infiltration pyelography, but was a very useful ally. He did not think that this new method was so certain in the diagnosis of malignant disease as the older method of procuring photographs of the renal pelvic outline. Excretion urography was of great value in tuberculous disease of the kidney, especially in bilateral cases. He was of the opinion that it was dangerous to perform bilateral simultaneous ascending pyelography in cases of tuberculosis. In the future he believed that intravenous urography would be practised as a routine, in the same way as a complete *x*-ray investigation. Dr. PHILLIPS quoted a case of hydronephrosis situated in the female pelvis, which was diagnosed by means of excretion urography. Mr. A. H. BURGESS said he thought that ascending and descending pyelography were better terms than those used by the previous speakers. He agreed with Mr. Dobson that bilateral pyelography by instrumentation was very dangerous in cases of tuberculous disease, in which descending pyelography was much safer. The main advantage of the excretion method was that the shadows seen were the result of the kidneys working under their usual physiological conditions, and that their true physiological function was thereby estimated. Mr. VAUGHAN HUDSON referred to a case of Dietl's crisis investigated by this method. No shadow was seen immediately after an attack, but was only obtained by injecting another dose of uroselectan some time later.

The PRESIDENT said that the position of descending pyelography was assured as a means of investigation. He thought that the excretion method would be of great service in controlling the results of operation such as nephropexy, etc.

Mr. OGIER WARD, in reply, said that healthy kidneys usually showed a shadow, but that there was a risk of missing it, since the shadow was only faint. This was very easy to do, especially in fat people, in cases badly prepared, and when the photograph was taken too late. He considered that the term "excretion urography" was the best term to use for this method.

SECTION OF OBSTETRICS AND GYNAECOLOGY

Thursday, July 23rd

MENORRHAGIA NOT DUE TO UTERINE DISEASE

The subject chosen for consideration by the Section at the second session was the causation and treatment of menorrhagias not due to uterine disease. The discussion was opened by Dr. A. S. PARKES with a paper on the physiological aspects of menstruation. Dr. Parkes took up the standpoint of the experimental physiologist, and in an endeavour to homologize the menstrual cycle of the primates with the oestrous cycle of the lower mammals first considered certain of the fundamental processes involved in the latter. He said that all Old World monkeys appeared to menstruate, and to have a cycle essentially comparable with that occurring in the human. It was necessary to suppose that whereas the pre-menstrual development of the uterus was dependent upon the presence of the corpus luteum, the actual factor causing necrosis and breakdown of the epithelium was not set in action by the atrophy of the corpus luteum, though operating at the same time, and that it was independent of any morphological ovarian cycle. Evidence had lately become available as to the site of origin of the substance concerned, which was probably hypophyseal. From the point of view of the factors concerned in menorrhagia unaccompanied by uterine disease it was evident that the necrosis factor was of prime importance. In cases of menorrhagia the morphological cycle in the ovary might be abnormal, or even entirely suppressed, and a condition might be found analogous with that in the non-ovulating monkey, except that the period of destruction of the endometrium was prolonged indefinitely. This appeared to point to the possibility that the factor causing necrosis lost its normal cyclic activity, and functioned persistently. If such an explanation could be substantiated an important basis would have been found for the experimental attack upon the problems of menorrhagia.

Dr. J. YOUNG (Edinburgh) followed with a paper in which the pathology, clinical features, and treatment were discussed. Briefly, he concluded that except after a recent

puerperal infection or gonorrhoea, inflammation of the endometrium or myometrium was a rare cause of irregular or excessive uterine bleeding. There was evidence that in a large majority of such cases the uterine pathology —the endometrial proliferation and congestion, and the myo-hyperplasia—and the symptoms were dependent upon aberration of ovarian function. The most common recognizable causes of this aberration were childbirth and general organic disease. The speaker considered that the terms "chronic endometritis," "chronic metritis," "fibrosis uteri," and "subinvolution," applied to the pathology found in irregular and excessive uterine bleeding, were quite inappropriate. The diagnosis in such cases rested upon an absence of a gross pathology—tumours, placental remains, tubo-ovarian inflammatory masses, etc. —and the appearances found in the endometrium after curettage. The treatment consisted of curettage, ovarian therapy, or, in intractable cases, the use of sterilizing doses of radium or *x* rays.

Professor FRITZ LAQUER (Frankfort) spoke on the influence of hormones upon menorrhagia. The ovaries and the pituitary glands exercised particular action upon the female generative organs. The hormone was present in large quantities in the urine of pregnant women. It was not absolutely necessary to use a crystalline preparation. Standardization by animal tests should be carried out. A certain number of cases were benefited by ovarian hormone, but cases remained in which no effect was observed. The therapeutic value of corpus luteum hormone was very little known. In the speaker's opinion its function could very often be taken over by the hormone of the anterior pituitary. The presence of this hormone could also be demonstrated in the urine of pregnant women, and this could be used as a means of diagnosis of early pregnancy. The watery solution of anterior pituitary was not very stable, being very susceptible to high temperatures. For therapeutic uses small doses stimulated, while large doses inhibited, ovarian activity. Combined treatment by ovarian and hypophyseal hormones should theoretically make it possible to control the action of the ovary.

Dr. H. GARDINER-HILL, speaking as a physician, referred to the relation of menorrhagia to general medicine. The cases presenting no obvious pathological lesions were usually related either to circulatory disturbances, the haemorrhagic diathesis, or to disturbances of the endocrine system. Hypertension was a not uncommon cause of bleeding. In the second type of case there was generally a history of epistaxis, or bleeding from the intestines, and so on. This was associated with a diminished number of blood platelets. In the endocrine type precocious development was frequently found, and skeletal abnormalities were present. This favoured the view that the ovarian secretions were abnormal. As regards the thyroid, if myxoedema developed before the climacteric—a rare occurrence—instead of amenorrhoea, menorrhagia was very commonly met with. In his own experience, on the other hand, hyperthyroidism was also more generally associated with amenorrhoea. Pituitary abnormalities were also associated with amenorrhoea.

Mr. J. ST. GEORGE WILSON (Liverpool) outlined the treatment of polymenorrhoea. The simplest method was curettage; a high proportion of cases were cured by this measure alone. Another form of treatment was by resection of the ovaries, or excision of the obvious cystic portions of them. Hysterectomy nowadays he thought was generally unnecessary. He advocated the vaginal route if hysterectomy had to be performed. As prolapse was often present as well, this rendered the operation comparatively easy. The treatment he employed now was curettage, followed by the introduction of radium. The dosage of radium employed was of importance; he usually used 2,500 mg. hours in multiparous patients. He had found deep *x*-ray therapy very satisfactory with old multiparae. The treatment of younger women was not so simple, since castration was not aimed at. There was one drawback—with frequent applications, patients were inclined to get dissatisfied, and to cease attending.

Dr. ZUCKERMAN discussed the oestrous cycle in monkeys. Two theories had been advanced to explain the cause of menstruation: one that some influence had been removed, the other that some exciting cause was responsible. Hartman had found that injections of anterior pituitary lobe invariably caused bleeding so long as the ovaries were present. Bleeding occurred some little time after the injections had been stopped; this suggested that the bleeding might be due to removal of this substance. Dr. W. LANGMUIR WATT recalled his experiences when working under Kelly and Bland-Sutton, and in Vienna and Dublin. The treatment of these cases with deep *x*-ray therapy was comparatively simple. The complete ovarian dose was 35 per cent. of the dose which would cause erythema of the skin. In his cases of temporary sterilization the earliest return of function was in three months, the longest was in three years. In women over 40 the full dose could generally be given. As a general rule, there was one period after treatment, generally a severe one. Severe menopausal symptoms did not usually occur. *X*-ray treatment of the pituitary had been followed by marked improvement in the symptoms; when indicated, it was safe, and gave good results. Dr. MARTINDALE made a plea for the use of *x*-ray therapy in non-malignant cases. She had used it since 1914, and was, as far as this country was concerned, a pioneer. Now that the technique was so greatly improved she thought that the method should be more generally employed. The patients felt so well afterwards. She did not see much advantage in radium, except that it was practically fool-proof. The after-results of radium were not yet well known. Dr. DAWSON (Otago) had thought until this discussion that the anterior pituitary hormone could act only in the presence of the ovaries. That theory was apparently now blown sky high. Mr. EARDLEY HOLLAND thought that the discovery of the connexion between the pituitary and the sex functions was as romantic as the discovery of insulin. As gynaecologists they must be physicians as well. Blood counts, platelet counts, and coagulation times should all be estimated in cases like these. He would like to have a clear explanation of the influence of the thyroid gland on menstruation. He felt doubtful whether a very high blood pressure in itself could cause menorrhagia. As regards the relative merits of radium and *x* rays, he confessed that his own faith in radium was somewhat shaken. With *x* rays temporary sterilization could be procured; with radium such effects were very uncertain. The advantage of radium to the gynaecologists was that they were able to carry out the treatment themselves. Mr. ERIC STACEY (Sheffield) said that no one had yet suggested what activated the anterior lobe of the pituitary. He had noticed that many of these cases had ovaries which were over-folliculized. So far, they had arrived at no satisfactory method of hormonic treatment of menorrhagia. Dr. PAYNE wanted to know whether the early diagnosis of pregnancy could certainly be made by finding the presence of hormones in the urine. Professor LAQUER replied that a positive decision could be made in almost all cases of early pregnancy as early as fourteen days. Certain pathological conditions gave a positive finding, but these were very rare. Dr. PARKES thought that it would probably be found that anterior pituitary preparations acted upon the accessory sexual organs quite apart from any action on the ovaries themselves. Dr. YOUNG (Edinburgh) thought that the day of extirpation of pelvic organs for this type of case had gone by. Preg-

nancy diagnosis tests were now carried out in various laboratories in this country. In 98 per cent. of cases the result of the test was correct.

SECTION OF DISEASES OF CHILDREN

Thursday, July 23rd

WORK OF A CHILD GUIDANCE CLINIC

In his opening paper on this subject Dr. BERNARD HART explained that the child guidance clinic had come into being to deal with a fairly well-marked group of patients known to every practitioner, and commonly called "difficult" or "problem" children. The list of disturbances from which such children suffered had long been recognized, but their effective treatment presented many difficulties. Of recent years there had been a change in the method of approach, which the speaker described as a progression from an ethical to a physical conception, and thence to one predominantly psychological and biological. Only when all the complicated factors involved in the child's condition had been thoroughly investigated and appraised could appropriate treatment be instituted. It was important to begin with a conception of the child as a psycho-physical organism reacting to an environment composed of material, mental, and social constituents, any of which could be at fault; the preliminary investigation must concern itself with all these things. After this there must be some adequate machinery for securing a modification of environmental conditions where necessary. The requirements of this machinery, said Dr. Hart, could obviously not be met under the usual conditions in a hospital out-patient department; and in sketching the development of the idea of the child guidance clinic he referred to the pioneer work carried out in America, and extended to this country through the generosity of the Commonwealth Fund. The essential feature of such a clinic consisted in the employment of a team of three persons, a psychiatrist, a psychologist, and a social worker. The psychiatrist was the head of the organization, and in addition to the investigation of the child's mental state he should also be responsible for a general physical examination, paying particular attention to the metabolic disturbances so frequent in difficult children. The psychologist had to investigate the child's intellectual equipment, while the social worker obtained full information with regard to the environmental conditions and past history of the child. In discussing the general objects of the child guidance clinic Dr. Hart spoke of the prevention of delinquency and the close association between the clinic and the children's courts. A further prophylactic function of the clinic was concerned with the psycho-neuroses, and possibly also with actual psychoses which it was hoped might be prevented in later life by adequate attention to the child. Dealing finally with certain criticisms Dr. Hart admitted the disadvantages of the team approach, but thought that these were clearly outweighed by the advantages. The costliness of the scheme was formidable; but an important function of the clinic was training of the workers to carry on the ideas underlying the work to the schools, juvenile courts, etc.; this must be set against the cost of an individual case. He pleaded, in conclusion, for a catholic point of view, so that each case could be considered from the widest possible angle and not treated along the narrow lines of any one school of thought.

Dr. W. MOODIE described in more detail the actual working of a child guidance clinic. Despite the description of the team employed, he said, the clinic was not so complex as it sounded. It was possible in many cases to give direct advice to parents on the first visit and so clear up the child's troubles, or it might be necessary in slightly more difficult cases to enlist the help of the educational psychologist, who was a very valuable help to the clinic, since 20 per cent. of all patients had some difficulty in learning as a basis of their trouble. In another group of cases something further was required, and the parent or child had to be seen more than once; while with a residue of about one-third of all the cases handled the full services of the clinic were called upon. Dr. Moodie likened the psychologist and the social worker to the laboratory and the *x*-ray department of the ordinary hospital out-patient department. The psychologist had to apply the intelligence tests in a highly skilled manner, while the social worker was of inestimable value in effecting changes in the environmental factors so often behind the child's disorders of conduct. He thought the child guidance movement went further than individual methods could ever go, but it was a mistake to suppose that the clinic merely made things easy for the child.

Dr. NOEL BURKE, dealing with the methods used in a clinic, emphasized the necessity of impartiality between the various schools of psychological theory and between the mental and physical views on the causation of problem children. He described the methods developed in the child guidance clinic of the Jewish Health Organization since 1927, and showed how each member of the team attempted to get as wide a view of the case as possible. He gave a brief analysis of the results of the first 200 cases, in which three-quarters were benefited in a varying degree and only nineteen could be called failures. He pointed out that clinics were expensive to run, but justified the high cost on the grounds that the community would gain in the long run and the next generation would grow up with a better idea of parenthood. Dr. G. M. BLUETT (Guildford) asked what practitioners were to do when there was no guidance clinic within easy reach, and whether there was any literature available for mothers who could not get to one of the clinics. Dr. J. HUTSON (Barbados) asked if the psychologist at a child guidance clinic was a medical practitioner.

The PRESIDENT (Dr. H. C. Cameron) said he had first observed many years ago how many cases of functional nervous disorder in childhood masqueraded as physical defects, and that the mother was responsible for this in the vast majority of cases. He also mentioned how much fatigue one saw in a maladjusted child, which was closely linked to the metabolic side of the question. He was not a great believer in propaganda by means of pamphlets. Dr. D. NABARRO referred to the relation between congenital syphilis of the nervous system and the delinquent child.

CONTROL OF INFECTIONS

Dr. D. NABARRO opened the discussion with a paper by himself and Dr. A. G. SIGNY on the prevention and control of measles, scarlet fever, and diphtheria in institutions and the home. Dealing first with diphtheria, the speaker outlined the present-day knowledge of the Schick test, pointing out that the "diphtheria period" of greatest susceptibility lay between 6 months and 5 years of age. He then described various methods of active immunization, recommending a toxoid-antitoxin mixture ("T.A.M.") as the safest. For the prevention of diphtheria in institutions he urged that all patients admitted should be swabbed for the possible presence of diphtheria bacilli; all sore throats or nasal discharges occurring in hospital should also be swabbed. Everyone in contact with a patient with a positive swab should be Schick-tested and the Schick-positive cases passively immunized with concentrated antitoxin. Dr. Nabarro especially suggested that all permanent staff should be immunized on admission. Dealing next with scarlet fever he described the Dick test, pointing out that in an early case it did not give much help in diagnosis. In an

epidemic, passive immunization with concentrated serum was of great value, and active immunity was also a useful method to apply to the permanent staff. In cases of operation on the nose and throat it was a good plan to Dick test the patient beforehand and to give a prophylactic dose of serum to those who reacted positively. With regard to measles Dr. Nabarro mentioned the difficulties of obtaining human convalescent serum, and pointed out that recently good results had been reported by using the blood of any adult who had previously had measles. The serum might prevent an attack of measles altogether, or the attack might be attenuated. He recommended a dose of 5 to 7 c.cm. of serum according to age, and reported that out of 625 cases injected with serum where he had observed the results 98.1 per cent. were protected, and only one severe attack of measles occurred in this group.

Dr. R. MASSINGHAM outlined a few of the measures which could be used in the control of infectious diseases, in addition to those made possible by the modern discoveries of the Schick and Dick tests. He emphasized how convalescent serum had revolutionized the outlook on measles, stressing the complete harmlessness of its use. Not only were patients protected against what might be a fatal disease, but in institutions the tedium and worry of quarantine was removed. The production of the attenuated attack was probably what should be aimed at. He found patients very willing to give blood for this purpose, and 500 c.cm. could be easily and safely taken. With regard to the spread of diphtheria and scarlet fever Dr. Massingham stressed the part played by the sick nurse who remained on duty too long before reporting sick, under a quite mistaken idea of what her moral code should be. Bed isolation, with a scrupulous use of separate utensils, instruments, gowns, etc., was a most important measure in institutions, and sterilization by means of steam was of great value. It was also important to see that toys, pencils, etc., did not get passed from child to child in schools. He thought that a rather stronger dose was needed in the Schick test for workers in institutions, and preferred the T.A.F. preparation for immunization against diphtheria.

Dr. A. I. SIMEY (Exeter) spoke particularly of the prevention of the infectious fevers in schools. He had found diphtheria and scarlet fever comparatively rare in a big public school, and did not consider routine skin testing and immunization advisable unless an epidemic broke out. He had found concentrated scarlet fever antitoxic serum very valuable, not only for that fever, but also for septic conditions; both for this and for diphtheria routine swabbing was of great help. With regard to measles Dr. Simey thought that this should be "got over" before the public school age, either by some scientific measure or by some more primitive method of allowing children to catch it from a known case and have the disease under proper supervision. He emphasized the importance of a pure milk supply in preventing the infectious fevers, and in conclusion said that he thought much could be done by scientific dietetics towards building up a satisfactory resistance to disease in childhood. Dr. K. TALLERMANN asked if there was any scientific evidence to support the often quoted opinion that immunity to diphtheria in infants was conveyed through the *mother's milk*. Dr. J. D'EWART (Manchester) spoke of the difficulty of the nasal carrier of diphtheria, and mentioned that he had recently had success with the ray treatment of such cases. He doubted if immunization of all entrants to hospital against scarlet fever was worth while, in view of the mild nature of the disease. He noticed that the surgical patients developing puzzling hematous rashes after operation were nearly always admitted immediately prior to the operation; perhaps other children became immune after a short stay in the general wards. He had used simple parental blood in the prophylaxis of measles with great success. Dr. TERTIUS CLARKE pointed out that there were no cases of scarlet fever in Malaya; and yet the infant population was largely Dick-positive, and slowly became Dick-negative, just as it did in countries where scarlet fever was rife.

SECTION OF PATHOLOGY AND BIOCHEMISTRY

Thursday, July 23rd

UNDULANT FEVER CONVEYED BY MILK

Sir WELDON DALRYMPLE-CHAMPNEYS, opening the discussion, said that systematic examination of milk supplies in Great Britain, if possible by guinea-pig inoculation, were badly needed. But if, as could hardly be doubted, these revealed that a considerable proportion of unpasteurized milks contained *Br. abortus*, what was the explanation of the small number of human cases of undulant fever so far discovered? Thirty-four definite cases of endemic origin in England and Wales and five in Scotland were known to him. In Rhodesia, where contagious abortion was not so rife as in this island, Bevan reported more than two hundred human cases, and in the United States 1,305 cases were reported during 1929. The speaker predicted that further investigations would show that undulant fever was much commoner with us than would appear at present, a large proportion of the infections being so slight that the patients never called in a doctor. It should not on this account be taken lightly, for undulant fever was a disease full of unexpected tricks, with an epidemiology still shrouded in mystery.

Dr. A. G. SHERA (Eastbourne) gave an account of four cases of undulant fever. The first patient was a youth of 16 years admitted to hospital, the second a member of the visiting surgical staff, the third a boy in one of the schools, and the fourth a former house-surgeon. The visiting surgeon had not been in actual attendance on the first case, but had attended the school in which the third case had occurred. The house-surgeon was engaged to be married to the sister in charge of the ward in which the first case had been nursed. The last two patients became ill simultaneously, but direct contact between them all had not been definitely established. The source of the infection had not been traced. There had been, however, an outbreak of contagious abortion within a few miles of the farm where the first patient lived. Blood cultures in cases one, two, and four, had failed to demonstrate the organisms. The maximum agglutinations were 1 in 5,000, 1 in 2,500, and in two 1 in 250. The titres, the speaker thought, ran parallel with the severity of the cases, and a drop was a good prognostic sign.

Dr. A. V. NEALE (Birmingham), in a paper on infantile diarrhoea, said that the rapid depletion of tissue fluids and loss of the normal intestinal secretions was a serious matter to the infant. Ketosis, together with disturbance in the acid-base equilibrium, was soon effected, and a variable degree of acidaemia or alkalaemia occurred. The delicate protective mechanisms in the bowel were quickly removed, and, by absorption, highly toxic products might enter the body. Renal, hepatic, and myocardial functions were often seriously disturbed by the dehydration and intoxication, and failure of the functions of these organs might directly determine a fatal issue. Three clinical varieties might be described. The first was acute ileocolitis of sudden onset, with diarrhoea, mucus and blood usually, and clinical evidence of abdominal pain and tenesmus. The disease was due to local infection of the bowel and absorption of powerful bacillary toxins into the circulation. The second or fermentative diarrhoea

was associated with acidic, gaseous, frothy, highly irritating, offensive stools causing excoriation of the skin. Dehydration was sometimes extreme, and the infant suffered from this, combined with starvation and physical discomfort. It might arise from irregular feeding or overfeeding with carbohydrates and fats. The third was acute alimentary intoxication in which there was severe diarrhoea with watery stools, vomiting, general collapse, subnormal temperature, rapid feeble pulse, scanty urine, clammy skin, pallor, and sighing respiration. Many of the characters of this illness suggested acute anaphylactic shock, and in great probability the cause was of this nature. As a rule little morbid anatomical changes could be seen in the bowel in any of these groups. In treatment first-class nursing was essential; the introduction of fluids to replace the excessive loss and the problem of feeding were the next concern. Blood transfusion was often invaluable.

Professor J. W. BIGGER (Dublin) said that they were ignorant of much concerning the relation of *Br. abortus* to man, but there were some points about which they were certain. Epizootic abortion was common in cows; *Br. abortus* was common in cow's milk, and might occasionally cause undulant fever in man. He could not agree with Sir Weldon that failure to diagnose the disease was responsible for the comparative rarity of undulant fever in the British Isles; on the contrary, he believed that critical examination would throw doubt on the validity of the diagnosis in many cases. He based this view on the fact that the diagnosis of the majority of cases was made dependent on the agglutination reaction, which he regarded as a very uncertain foundation on which to erect a diagnosis. If they accepted any mild fever and a positive agglutination as diagnostic of undulant fever they would undoubtedly have many cases, but Professor Bigger did not regard this as legitimate. For diagnosis the isolation of *Br. abortus* was the ideal, and failing this only a typical clinical condition, together with a high agglutination, should be accepted. The agglutination titre of serums (submitted for the Wassermann test) against *Br. abortus* had been tested in two series. One was carried out by himself at a temperature of 54° C., and the other by Dr. A. H. Thompson at 37° C. In both series they found a much higher proportion of positive results than those observed in other countries. Professor Bigger had obtained 20 per cent. positive at 1 in 20, and Dr. Thompson 32 per cent. at 1 in 25. In one individual Dr. Thompson observed a rise in titre from 1 in 25 to 1 in 1,000, and a fall to 1 in 125 during a period when the patient was under constant medical observation, and yet exhibited no evidence of undulant fever. The speaker believed that the organism could invade without infecting, and so give rise to the appearance of agglutinins; but these cases or those with only a mild fever should have some other name. They should not be called undulant fever.

Major L. P. PUGH said that he had had a case of infection in a man caused as the result of using live vaccines in a herd of cows. The organisms in this particular case appeared to be more virulent than usual, since a number of the animals became ill following injection. The Ministry of Agriculture's policy of using live vaccines was, he felt sure, the right one on the score of its success in treating heavily infected herds, and particularly because it diminished the tendency to complications such as endometritis, salpingitis, and sterility. He was interested in Dr. Neale's description of ileo-colitis in infants, because it had its counterpart in young calves; it would be worth considering whether there might be a direct transference from calves to infants. The investigation of these diseases called for a closer collaboration between the medical and the veterinary professions. Mr. E. M. PERRY said in his experience Mr. Rabagliati's estimate that 50 per cent. of the herds in this country were infected with *Br. abortus* was not an overestimate. He further pointed out that of infected herds from 30 to 90 per cent. of the individuals might be affected. This being so it was difficult to believe that ordinary strains of this organism were pathogenic to man. The usual method of entry of the disease into a herd was the introduction of a fresh beast which might slip her calf, or even carry it the full time and thus be a source of unsuspected infection. One or two abortions might occur during the first year, the number increasing during the second and third years, after which there was a dropping off until the herd became immune. The disease itself was a specific catarrhal metritis, and infection in the majority of cases resulted from the ingestion of contaminated foodstuffs.

MILK-BORNE STREPTOCOCCAL INFECTIONS

Lieut.-Colonel E. WILKINSON, I.M.S. (ret.), said he would deal only with scarlet fever and sore throat, quoting an epidemic of each. In the scarlet fever outbreak sixty-six persons were attacked in ten days, forty-four of them being attacked on the fourth and fifth days of the outbreak. At the same time about one hundred people were reported to be suffering from sore throat. All these persons were consumers of either milk or cream from an old-established firm of good reputation, and its premises, which included a milkshop, were clean. Haemolytic streptococci of scarlatinal Type II were obtained from the throats of some of the patients and from the dairyman's son, who, in the early stages of the outbreak, suffered from a "rough throat" and later desquamated. In the sore throat outbreak members of over one thousand families were affected, and sixty-five deaths occurred. The primary illness was in most cases follicular tonsillitis (often severe) which was in many instances accompanied or followed by complications, mostly of a septic character. All the patients were consumers of milk from a particular dairy, which was exceptionally well equipped with modern appliances, its milk being obtained from a number of local farms. Samples of milk from each farm were taken, and one of them was found to contain abundant streptococci; when the use of this milk was stopped the epidemic ceased. The farm supplying this milk proved to be a model of its kind; some of the cows, however, had been suffering from inflammatory conditions of the udders. Cultures from the milk failed to establish a definite connexion between the cows and the streptococci causing the throat infections. Some of the cows had been removed from the farm and could not be examined, so that positive proof was not established. In spite of this it seemed likely that when the milk from this farm—alone of the many supplying the dairy—was stopped and the outbreak ceased, the infection of the milk was secondary to infection of cows.

Dr. R. A. GLEGG (Lewes) observed that the second of the two outbreaks described by Colonel Wilkinson was of such magnitude as to call for special preventive measures. Medical practitioners could assist in tracing milk-borne infection if they ascertained and stated the source of milk supply when submitting throat swabs to municipal authorities. Representations had been made to the Ministry of Health to make compulsory the notification of sore throat and diarrhoea among persons employed in handling milk. Dairy farmers should be asked to post notices in their cowsheds asking employees to report if they or any of their families suffered from sore throat or other illness. The agriculture committees of the county councils should not be content to leave the inspections of the farms, dairies, and cows to the already overworked sanitary inspector, but should provide experts to assist him in this important part of his duties. Dr. E. N.

DAVEY said that he had seen two cases of undulant fever, and although unable to grow the organism he considered that an agglutination titre of over 1 in 125, an undulant fever chart, and leucopenia with relative lymphocytosis, provided sufficient data upon which to make a diagnosis. In three years' routine agglutination reaction of all serums submitted as possibly typhoid only 3 per cent. showed any reaction with *Br. abortus*. In a carefully guarded herd an outbreak had occurred apparently as a result of introducing a new bull, as the first three cows served by him aborted, although there had been no previous abortions in the herd for the past eight years. Dr. M. MAIZELS remarked that in infantile diarrhoea he found otitis media in 40 per cent. of post-mortems. He asked if the ears of all infants suffering from this condition should be drained. The administration of sodium chloride in these cases was not without risk, for it might displace the bicarbonate from the blood into the urine and increase the acidosis. Dr. H. W. C. VINES said that as a result of this discussion it would appear to the general public that another nail had been heavily hammered into the coffin of fresh milk as a food, for it was becoming increasingly evident that this fluid was merely a suspension of more or less pathogenic organisms. He felt that it was becoming a matter of real urgency that the public should be given clear guidance whereby diseases such as those discussed might be avoided.

Sir W. DALRYMPLE-CHAMPNEYS said, in reply, that he could not agree with Professor Bigger that any distinction could be drawn between invasion and infection. The agglutination test appeared to him, from the many hundreds of papers he had read, to be a reliable diagnostic method.

SECTION OF PUBLIC HEALTH (INCLUDING TUBERCULOSIS AND OCCUPATIONAL DISEASES)

Thursday, July 23rd

PUBLIC HEALTH PROBLEMS OF AIR TRAVEL

Sir GEORGE BUCHANAN, President of the Section, took the chair at the second session. He referred briefly to the importance of the subjects to be discussed, and mentioned that the Ministry of Health was taking an active interest in the hygienic problems which were developing as a result of increasing travel by air.

Dr. A. MASSEY (Coventry) outlined the novel public health contingencies introduced by aerial navigation, pointing out that journeys from distant infected countries could now be accomplished within the incubation periods of the major infective diseases. It would be necessary, therefore, for the health department of the passenger's ultimate destination to arrange for him to be kept under observation until the incubation period for such diseases scientific plague, cholera, small-pox, or typhus fever was over. of allowing er of introducing the mosquito hosts of yellow nd have the dis but special precautions would have to mphasized the imp ts in yellow fever zones to ensure that reventing the infecti ere mosquito-free. The holds of air- h t he thought much could to be safeguarded from rats. The ociards building up a satis ft crossing land might originate Ir. J.dhood. Dr. K. TALL reta were deposited in water itment ntific evidence to spect of such releasing would ettage ; aat immunity to diph system of excreta disposal isure alonough the mother's on long-distance machines. ion o the spoke of the diffic each centre of population tions and mentioned th us associated with these gene ly unne x-ray treatme eful consideration by the te if hy erectonization of all entr ublique and the Inter- often present a orth while, in v ion ; it was likely that paratively easy. had noticed tha ntrol of aircraft would ttage, followed by erythematous r nations. Dr. Massey e of radium emplo those admitted air-ports would com- health point of view, with seaports. He showed plans outlining the systems of water supply and sanitary provision on board the airships R 100 and the late R 101 ; these had been specially supplied by the Director of Airship Development, Carding-ton. Thanks to the steps being taken, there was no danger of any risk to the public health consequent on aerial navigation.

Sir GEORGE BUCHANAN said that progress had been made towards a general agreement on sanitary control. Dr. Massey's clear statement of the position had been very helpful. The degree of control to be exercised at the various air-ports would differ, but the previous history of seaport regulations had taught them not to impose too hurriedly panic restrictions, which would later become both inconvenient and unnecessary. Instances were cited to illustrate the way in which such limitations had already hampered air travel. It was necessary to think out the matter in advance. Influenza, encephalitis, and such infections with short incubation periods, might also constitute dangers ; these were already being considered by the Ministry of Health.

Sir MALCOLM WATSON congratulated Dr. Massey on his paper. There was one aspect of the yellow fever problem which he had not mentioned—the danger of the disease reaching the East Coast of Africa. The speaker regarded this as a probability almost amounting to a certainty, unless a strong sanitary policy was pursued. If a case of yellow fever reached East Africa in its incubation period it would almost certainly not be diagnosed ; and, even if it were, the disease would at once produce an epidemic. The Americans had the greatest difficulty in stamping out the disease at Panama. It was done by an elaborate anti-larval campaign, isolation of the patient in a mosquito-proof ward, and—to make the security greater—in a mosquito room inside the mosquito-proof ward. Even these precautions were not enough, and the city of Panama was fumigated three or four times in order to destroy the adult mosquitos. If such strict precautions were necessary in Panama, it would be realized that, in the absence of such, yellow fever would spread on the East Coast of Africa. The next step would be from Africa to Asia by steamer, and this appeared to him inevitable in view of the mosquito conditions existing in Bombay, Colombo, and other ports. Sir Malcolm reminded his audience that twenty or thirty ships without crews sometimes lay for months in South American ports. An epidemic of yellow fever in Asia would paralyse Eastern trade, and that would have a repercussion on Europe that would bring modern civilization to a standstill. If rubber alone, quite apart from foodstuffs like rice, etc., were not available from Asia (which supplied about £00,000 out of the £30,000 tons used), all electrical apparatus would be put out of action. Without electricity, ships and other transport, telephones, telegraphs, etc., it seemed to him that the dense populations of Europe would starve, and it would be a generation before things returned to anything like normality. Originally the danger of yellow fever spreading to Asia was considered as likely to come from the Panama Canal. So far back as 1915 he had pointed out that the real danger was the West Coast of Africa, and that as soon as it was possible to travel across Africa in ten days the danger would be great and the prevention of the spread of yellow fever be the most serious sanitary problem of the time. It was probably now possible to cross Africa by train and steamer in six days, if connexions were caught ; but air travel, which was making rapid progress in Africa, had brought the problem to the front. The speaker asked the President if he could give them any information as to the precautions now being taken to prevent the spread of yellow fever in Africa.

Dr. R. A. O'BRIEN asked if the smuggling of pet dogs in aircraft had ever caused rabies. Dr. E. H. R. HARRIES (Birmingham) asked if the incubation periods of plague

and cholera were correctly stated in the paper. Dr. L. P. LOCKHART (Nottingham) asked about the possibilities of transmitting disease as a war-time measure. Sir GEORGE BUCHANAN agreed with Sir Malcolm Watson about the importance of taking steps; the international consultations now in progress were actively cognizant of such conditions as those in Africa. The port of departure, not the port of arrival, was the vital point of attack.

Dr. MASSEY, replying, said his paper had been specifically limited to the conditions in Great Britain, but the needs of our Dominions were equally being considered. He had no special knowledge about the risks of the importation of rabies, but thought they required attention. The incubation figures in his paper were the outside limits

FUNCTION OF THE ISOLATION HOSPITAL IN MODERN PRACTICE

Dr. E. H. R. HARRIES (Birmingham) read a paper embodying an inquiry into the extent of the success achieved by the isolation hospital in respect of segregation and treatment, and also as a centre for teaching and research. Isolation had proved less effective in endemic than in epidemic diseases, but it was at times necessary view of local circumstances. Immunization on a large ale was so far only a counsel of perfection. The accom dation of these institutions was not being used to the best advantage, numbers of patients being admitted without sufficient justification from the standpoint of either preventive or curative medicine; this was especially so in diphtheria. The value of swabbing was overestimated, many apparently positive cases being proved eventually by the Schick test to be negative. On the other hand, the value of a timely dose of antitoxin on suspicion had been underestimated. Convalescent patients often occupied beds unnecessarily, the danger of infection in the later stages of disease having been overemphasized in the past. Many cases of scarlet fever could well be treated at home, especially now that the disease was so mild, and specific antitoxic therapy was available. This would necessitate altering the public outlook in the case of this disease easles and whooping-cough, however, ought to be more ten treated in hospital; again, the public should be educated in this matter. In treatment an important factor was team work; thus in toxic diphtheria repeated estimations of the blood sugar, and the administration of dextrose and insulin, should be associated with the taking of serial electrocardiograms. The case mortality in the Birmingham City Hospital had been reduced by nearly 13 per cent. as the result of such co-ordinated observation and therapy. More use should be made of the clinical material in isolation hospitals for instructional purposes, and medical students might well clerk in the wards. Research in this country was backward as compared with that on the Continent and in the United States. British studies were largely repetitive, and not original. The fever hospital (really a large children's hospital) was practically the only institution receiving cases of tonsillitis, and the early stages of rheumatic conditions might well be studied in it. Definite provision should be made for organized research, preferably in connexion with the universities and medical schools, so as to prevent unnecessary overlapping. The younger medical officers should be encouraged and helped to conduct original investigations, time being systematically allotted for this. Research workers from outside should also be given facilities.

Sir GEORGE BUCHANAN said that now was the time for stocktaking in public health, and for preparing new advances. This applied both to administrative questions and to the promotion of research. Dr. J. D. ROLLESTON agreed with Dr. Harries that the functions of an isolation hospital were those of isolation, treatment, teaching, and research. He quoted figures showing that a large number of patients were needlessly sent to hospital, as they were subsequently found to have no obvious disease, or at least were not suffering from any admissible infectious disease. In the serious infectious diseases isolation was desirable, not because it was hoped to reduce their incidence, but in order to secure adequate nursing and medical attention, removal to an isolation hospital of mild infections was needed in the case of inmates of schools and hospitals or institutions, where isolation could not adequately be provided. Dr Rolleston emphasized the need of impressing upon the student the importance of a study of fevers, whatever his subsequent career might be, and suggested that his attendance at a fever hospital should take place at an early stage of his clinical training, as such a study would bring him into relation with many other branches of medicine. In conclusion, Dr Rolleston maintained that the Metropolitan Asylums Board in the last years of its existence, and the London County Council had encouraged research in their fever hospitals and that as a result a not inconsiderate amount of work had been done in many fields. Dr R A O BRIEN asked how all could be considered well when medical students paid "a breathless series of visits" to isolation hospitals and later, as practitioners, never treated a case, while, on the other hand, 30 to 45 per cent. of patients certified as having scarlet fever or diphtheria were incorrectly diagnosed. Clerking was one way out of the difficulty. The speaker asked boldly for a re-examination of the whole system. Why not, he said, attach annexes to general teaching hospitals? Scarlet fever was not the scourge it had been in Murchison's time, and Dr Nabarro was showing in another Section of the Annual Meeting how efficient was the hospital control to-day of ward outbreaks of diphtheria, measles, and scarlet fever by Schick and Dick testing, and by subsequent active and passive immunization. The constant presence of the breezy criticism of the student in the wards was a good thing. Apart from carrier nursing, could one honestly say that this country had contributed anything original in the last thirty years to compare with intubation, Schick and Dick control, or measles control with serum? Had their able clinicians and medical administrators in the fever services been provided with a proper complement to their work by way of a research organization they might have been able to answer this question with confidence. Why was a pathologist thought essential in an average general hospital while there were, outside London, probably 30,000 beds in fever hospitals, the superintendents of which were pleading in vain for full-time pathologists? How many fever hospitals used to-day in suspected scarlet fever, as a routine, the helpful immediate smear, and the often decisive overnight culture on a blood plate?

Dr. W. E PORTER (Eastbourne), discussing the overcrowding of fever hospitals, pointed out the difficulties thrust on the patients' families and the general practitioner if such segregation of scarlet fever cases was not practised. Dr. D SUTHERLAND (Manchester) said that there was a great difference in various teaching centres as regards what was arranged in the way of lectures and demonstrations on fevers. In some this was very inadequate, and even in D P H courses there was carelessness in fulfilling the regulations at present in existence. The universities and the General Medical Council should take more definite steps. Classes were too large for good instruction. In Germany he had been much impressed by the success attending the practice of providing an annexe for infectious diseases in association with general hospitals. Such a scheme would centralize and intensify the work, and would benefit the training of nurses simultaneously. Economy and general convenience would be promoted by this arrangement. Dr. A T HAWLEY (Coventry) agreed that the teaching of medical students was inadequate. Nursing instruction on typhoid fever

was sadly deficient. Dr. L. P. LOCKHART (Nottingham) thought that clinical assistantships in fever hospitals should be multiplied. Dr. R. GELLATLY (Huddersfield) said that in the smaller hospitals there was a sad lack of pathological facilities, and great delay in diagnosis ensued. Notification was enacted by law, and the public health expert rather than the general practitioner should bear the responsibility for mistakes in diagnosis. The fever hospitals were also concerned in preventing the secondary results of infections, and could prosecute research if they were better centralized. Dr. MORGAN REES (Pontypridd) agreed about the inconvenience caused to the family. Mistakes were inevitable. Dr. J. HUTSON referred to a system in Barbados for segregating suspected cases. He thought it might be applied with advantage to Great Britain. Dr. HARRIS, replying, welcomed the discussion which had resulted. He felt that original research was still deficient, and urged the need of doing more in this respect.

ORGANIZED TREATMENT OF INFANTILE PARALYSIS

Dr. G. MURRAY LEVICK, opening a discussion on the organization of treatment for infantile paralysis, said the acute attack should be distinguished from its after-effects, and it was essential to deal with this disease in a less haphazard manner than was the custom at present. He outlined the diagnostic criteria, and described how, in East Sussex, skilled assistance had now been made available for general practitioners, both as regards swift diagnosis and immediate serotherapy. Details were given of the various lines of treatment, and slides shown of these being conducted at the Heritage Craft Schools, Chailey. Heliotherapy was of decided value, and the adverse report issued by the Medical Research Council should be disregarded. Intense red light was very beneficial for paretic muscles. Out-patient treatment for the later stages was provided at clinics, and the whole East Sussex area was now linked up with its central hospital. Correct posturing of the affected parts at the very outset of the disease, and the avoidance of pressure on the muscles by bandages, were of paramount importance. One of the commonest mistakes was giving excessive faradic stimulation for anterior poliomyelitis; only the single stimuli of the interrupted galvanic current should be employed at this time. All patients suffered concurrently from a profound neurasthenia, which needed special measures. Dr. Murray Levick pleaded for the provision of more facilities for the treatment of children coming from families with small or moderate means; at present, he added, only the very rich or very poor were being properly dealt with. It was surprising also that physical treatment was not included in the examinations or curriculum of the medical student. It was being carried on, consequently, without competent medical supervision. At the conclusion of his lecture Dr. Murray Levick demonstrated two cases to show how the methods described resulted in full development of function and bodily health to the utmost limit that could be expected. One important sequel was the mental recovery and intellectual development, attributable largely to the light treatment and the influence of the open-air life at Chailey.

Dr. E. H. R. HARRIES, who had taken the chair owing to the departure of Sir George Buchanan, referred to the public health aspects involved. Great patience was required, and protracted treatment was necessary for good measure to be obtained. Dr. H. B. GIBBINS (Eastbourne) asked how long the scanty costume of these children was generally under the weight or thickness of the wind-proof cotton coverlet was especially when sudden

SECTION OF NEUROLOGY AND PSYCHOLOGICAL MEDICINE

Thursday, July 23rd

THE PROBLEM OF SUICIDE

In this Section the day's proceedings were devoted to a consideration of the problem of suicide. The discussion was opened by Sir HUBERT BOND from the sociological aspect, by Dr. H. CRICHTON-MILLER from the psycho-pathological aspect, and by Dr. W. NORWOOD EAST from the medico-legal standpoint. These three introductory papers are printed in full in this issue of *the Journal*.

Dr. L. A. WEATHERLY (Bournemouth) considered that Dr. Crichton-Miller had possibly laid too much stress on the sex instinct and its frustration as a cause of suicide. With reference to the half-hearted attempts at suicide of some hysterics, some, unfortunately, were successful. When insomnia was a prominent symptom it needed prompt and definite treatment. Most unfortunately, the physician who attempted to get rid of mental pain and induce refreshing sleep was sometimes stigmatized as a creator of a drug habit. In his many years of practice Dr. Weatherly had prescribed many such drugs, and he was not aware of having created a drug habit in any single individual. Dr. A. LEWIS pointed out the importance of investigating the total biological changes in the patient, and the inadequacy of explanations in purely "psychological" terms. He discussed the biological and psychological factors in relation to suicide, and pointed out the important bearing of current social and ethical values on the incidence of suicide. Suicides could be divided into three main groups: (1) psychotics, (2) psychopaths, and (3) those mentally and physically normal. Dr. N. E. WATERFIELD (Great Bookham) did not consider that fear of the consequences determined a murderer to commit suicide. The suicide was rather part of the same act, since it was carried out in almost every instance immediately after the murder. Were fear of the consequences the determining factor, the suicide was more likely to be deferred. He also cited cases illustrating the contention that many suicides occurred as an overwhelming desire to escape from an intolerable situation. Dr. T. W. SCOTT (Malay States) quoted a case of successful suicide, and gave an outline of the arguments by which he tried to dissuade the victim from his act. He inquired if any other effective measures could have been taken. Dr. E. F. HOARE (Lewes), speaking as coroner for East Sussex, said he was very glad to find so much interest in the subject. For a long time he had kept a record of the cases of suicide with which he had to deal. As regards motive, he would classify his cases as follows: mental diseases, 26; domestic and financial worry, 20; disease or dread of disease, 13; insomnia, 7; love disappointments, 4; grief, 4.

The PRESIDENT, Sir James Purves-Stewart, was sceptical as to the value of statistics. He considered it very important to ascertain the family history in every case of suicide, as an inherited tendency to mental disease was frequent. Some suicides occurred from the highest possible motives; Captain Oates of the Scott polar expedition was an example. Dr. R. G. GORDON (Bath) asked if the origin of suicide were not something deeper than the product of symptoms such as insomnia. It was possible that the real understanding of suicide would arise from a study of the psycho-biological make-up of the individual. If the personality was harmoniously organized, suicide was not possible. Was there any way of recognizing those cases which were not capable of such harmonious organization, so that we might know of potential suicides and undertake preventive treatment? Dr. D. RICE (Norwich) referred to a group of non-intentional or accidental cases of suicide who resorted

to self-injury as a physical counter-irritant to pain, physical or mental, with fatal results. Such cases as he had seen of successful starvation had all been shown to have serious disease of the gastro-intestinal tract. Dr. J. BIRCH considered that heredity had no significance in suicide, but that suggestion was of the greatest importance. He gave instances of consecutive suicides in a particular district, the later ones apparently being induced by the preceding suicides. Dr. F. R. P. TAYLOR (Hellingly) spoke of the value of the social worker and the out-patient clinic in attempting to deal with early mental disorders. It was hoped that many potential suicides would thus be assisted.

SECTION OF OPHTHALMOLOGY

Thursday, July 23rd

OCULAR PALSIES

The meeting was opened by Dr. GORDON HOLMES with a paper on ocular palsies. He laid stress on the three main and distinct groups into which these could be divided: (1) paralysis of the ocular muscles due to disease of their motor nerves or nuclei; (2) conjugate palsies; and (3) supranuclear palsies. Paralyses of ocular muscles were of great importance to the ophthalmologist owing to their relative frequency, and these could be divided up into (*a*) nuclear palsies, (*b*) stem palsies, and (*c*) root palsies. These three groups were discussed at length from the point of view of etiology and differential diagnosis; and the importance of root palsies in cases of arterio-sclerosis of the arteries at the base of the brain was stressed. Dr. Gordon Holmes ended his most instructive paper with a description of the conjugate and supranuclear lesions, with diagrams showing the probable site of the lesions in different cases.

Mr. O. GAYER MORGAN discussed a group of cases where certain abnormalities of the pupil were associated with a pathological absence or diminution of the tendon-jerks. He pointed out that the recognition of this benign condition was of great importance, as it might so easily be mistaken for a specific one. The differential diagnosis could be made by a careful consideration of the exact reaction in convergence, as pointed out by Dr. Adie—the reaction being brisk in the true Argyll Robertson pupil and extremely slow in the case of the group under discussion. The Wassermann reaction in these cases was always negative.

Dr. THEODORE WHITTINGTON read a very interesting paper on the results of his investigations into the post-encephalitic ocular complications of 174 children. He pointed out that epidemic encephalitis was of interest to the ophthalmologist because of the following points: (1) as regards diagnosis, because the ocular phenomena were of great importance, both in the acute and chronic stages; (2) the peculiarity of the ocular signs, some of the most extraordinary of which only occurred in this disease; (3) the correlation of the symptoms in this disease helped to throw light on the neurology of the ocular movements; (4) the great benefit obtained by the use of the belladonna group of drugs in chronic Parkinsonism, and some of the visual effects of these drugs. In the acute stage the presence of papilloedema was decidedly against the diagnosis of encephalitis. Among the chronic cases the main points to be noted were the infrequency of ptosis, the number of cases with diminished or absent pupil reactions, the absence of paralytic squint—but the remarkable number with concomitant external strabismus—and the onset of oculogyric crises. He ended his paper with a description of some of the visual effects of large doses of stramonium—paresis of accommodation and dilatation of the pupil—which could be counteracted by glasses or by eserine.

In the discussion Mr. MADDOX, the President, raised the question as to why they saw so few cases of spastic paralysis of the ocular muscles. Others who took part in the discussion were Mr. GIRI, Colonel WRIGHT, Mr. BISHOP HARMAN, and Mr. MASON.

DR. SHEEHAN'S THERMOPHORE

The main discussion was followed by an interesting paper by Dr. WILLIAM H. CRISP of Denver, Colorado, on the thermophore of Dr. Sheehan as an aid to treatment of inflammatory conditions or tumours of the eye. He showed the instrument itself, and explained the method of its use, giving some personal experiences in the treatment of serpiginous ulcer and growths at the limbus. The instrument contained its own thermometer, and the actual heat used at the nickel-plated brass applicator varied with the type of tissue under treatment. This temperature had been worked out with great care by Dr. Sheehan in experiments on animals. Dr. Crisp gave some remarkable figures of the treatment of a series of twenty-two cases of serpiginous ulcer. He concluded by describing the type of anaesthesia required and the method of application by firm and continuous pressure. Colonel WRIGHT said that he had used the apparatus, and thought very highly of it. The meeting concluded with a series of lantern slides, chiefly of orbital conditions, by Dr. CLARK SOUTER (Aberdeen). The photographs excited general admiration for the way in which they demonstrated quite minor points by their perfect definition.

Before concluding its business the Section adopted two resolutions: one recommending the Council of the Association to urge on the Ministry of Transport the desirability of having road signals which depend on form as well as on colour; the other recommending the Council to point out to the General Medical Council the desirability of giving students opportunities to study the care and treatment of ophthalmia neonatorum, the best time for such instruction being during attendance on the course of fevers.

SECTION OF ANAESTHETICS

Thursday, July 23rd

CARBON DIOXIDE IN POST-ANAESTHETIC RESPIRATORY COMPLICATIONS

At the second session of the above Section, Dr. S. THOMPSON ROWLING, a vice-president of the Section, occupied the chair. Dr. J. Ross MACKENZIE (Aberdeen), opening a discussion on this subject, read a paper entitled "Observations on carbon dioxide gas as a prophylactic and curative agent of post-anaesthetic respiratory complications." He emphasized three important advantages which accrued from the use of this gas: (1) the prophylactic action of carbon dioxide against the onset of respiratory complications; (2) the protection afforded to patients who came up for operation with concomitant respiratory disability; and (3) the curative action of carbon dioxide when post-anaesthetic respiratory complications had occurred. As a result of hyper-ventilation with this gas the respiratory system was continuously in the position of inspiration, with the bronchioles and the air sacs expanded. Records of a series of consecutive abdominal operations demonstrated the extreme rarity of serious respiratory sequels provided the pulmonary system was kept patent during the surgical procedure and for twenty-four hours afterwards. Such complications as did occur invariably cleared up rapidly when treated by hyper-ventilation with carbon dioxide. Describing his technique, Dr. Ross Mackenzie said that the percentage of carbon dioxide, the duration of the period, and the frequency of administration should be regulated to the requirements of the individual patient. He remarked that the only untoward effect upon the organism as the result of inhaling 6 per cent. carbon dioxide during a

period of two hours was diuresis and increased acidity of the urine. In conclusion, he said that carbon dioxide gas should be available in every operation theatre and in every surgical ward; that, when used with discrimination, the gas was a valuable adjunct to general anaesthesia.

Dr. S. THOMPSON ROWLING (Leeds) said that this gas was of great value in that it enabled the patient to leave the theatre with a brisk corneal reflex. The PRESIDENT considered that practical difficulties militated against the extensive use of this gas in nursing homes; it was not easy to transport heavy apparatus from place to place, and, also, it was necessary to instruct nurses in the proper method of administration. Dr. F. T. EVANS said that he had found carbon dioxide of considerable value in relieving hiccup. He cited a case in which he had employed this method of treatment, and inquired if there was any objection to the prolonged administration of the gas. Dr. R. J. CLAUSEN congratulated Dr. Mackenzie on his results and on the systematic application of the method. He suggested that a simple machine was required which did not need the constant attendance of an expert. In this connexion he mentioned the "Carbetha" apparatus made by Messrs. Siebe, Gorman, and Co., Ltd.; although designed primarily for industrial use, it provided an efficient and safe method for administering the gas. He thought that a mixture of carbon dioxide and air could advantageously replace a mixture of the former gas and oxygen.

Replying to the points raised in the discussion, Dr. MACKENZIE said that it was only necessary to give carbon dioxide until the patient was breathing deeply; its use could then be temporarily discontinued. He had observed no harmful effects from repeated administrations.

PRE-MEDICATION

Dr. E. S. ROWBOTHAM said the modern conception of pre-anaesthetic medication implied that the patient should be unconscious in bed before the administration of the anaesthetic. Reviewing the drugs for this purpose he described the properties, methods of administration, and cases illustrating the use of paraldehyde, tribromethyl-alcohol, and the barbiturates. Dr. Rowbotham confessed a personal preference for either paraldehyde or nembutal; he preferred the former for children, because the barbiturates must be administered by the mouth or by the rectum. For adults nembutal gave equally good results, and post-operative restlessness, when present, was slight. Combinations of drugs acted more powerfully than when they were administered alone; what was known as basal narcosis marked a distinct advance in the administration of anaesthetics.

Dr. HUGH R. PHILLIPS stressed the importance of the use of morphine or omnopon (with atropine and hyoscine if desired) in every case in which paraldehyde, avertin, or any of the barbiturates were used. He regarded paraldehyde as the best form of pre-medication in children, but he administered the drug in saline and not in oil. He found nembutal satisfactory when given in capsules, but, in his experience, surgeons objected to intravenous pre-medication. An important point was the increase of work for the nursing staff entailed by the use of basal narcotics. Dr. I. W. MAGILL paid a tribute to Dr. Rowbotham's pioneer work on the use of paraldehyde as a rectal anaesthetic. Basal narcosis, he considered, had passed the stage of mere experiment, but it remained for anaesthetists to learn how to make use of them. It was advisable to warn the surgeon and the patient's attendants of the long somnolent state which might follow anaesthesia. Dr. Magill preferred nembutal to other basal narcotics; but in children, in whom intravenous injection was difficult, he preferred rectal paraldehyde, with its wide margin of safety. The perfect drug had yet to be discovered, but the principle of basal narcosis before anaesthesia was, in his opinion, quite definitely established. Dr. RONALD JARMAN considered that it was essential for the patient to have adequate pre-medication in order to allay fear. It should be the aim of anaesthetists to put the patient asleep in bed, and allow him to wake up only when all discomfort was over. Basal anaesthesia made it possible to reduce the amount of volatile anaesthetic administered. He thought avertin ideal, and considered that paraldehyde was very successful. He had had one serious case with sodium amytal, and he preferred to administer nembutal intravenously rather than by the mouth. Dr. F. T. EVANS preferred avertin to other basal narcotics. He detailed his experiences with this drug in combination with spinal analgesia. The rule he adopted was to give avertin, and, if the fall in systolic blood pressure did not exceed 20 mm. Hg, to proceed with spinal analgesia; if the fall in blood pressure was greater than this figure he withheld it.

Dr. F. B. PARSONS (Cambridge) drew attention to the chemical and pharmacological properties of the basal narcotics. He was interested to hear Dr. Rowbotham state that fatty degeneration of the liver was found post mortem in a case which terminated fatally after the administration of avertin, because animal experiments had led him to believe that this might be a possibility. He stated that, as a rule, non-volatile anaesthetics were slowly excreted while volatile anaesthetics were eliminated rapidly by the lungs. Paraldehyde should therefore be regarded as a volatile anaesthetic. Dr. PUGIN MELDON (Dublin) mentioned that at first he was afraid that nembutal might destroy blood corpuscles, on account of the high pulse rate which frequently followed its administration. He had heard of two cases of attempted suicide with the drug, in which 30 grains were taken. The only effect was prolonged coma. Dr. R. J. CLAUSEN was glad that Dr. Rowbotham's early work with paraldehyde had received adequate recognition. He hoped that the newer drugs would not cause the older remedies such as morphine and hyoscine to be forgotten. It would be unfortunate if the use of these drugs became universal for there was always the danger that they would be used without adequate experience and care, and, possibly, in excessive dosage. Dr. E. W. STRANGE (Wolverhampton) detailed a personal experience when he received morphine and hyoscine as preliminary medication. Subsequently he had no recollection of receiving ether. The PRESIDENT considered that very good results could be obtained with morphine and hyoscine. He regarded the use of avertin as risky.

In reply, Dr. ROWBOTHAM stated that basal narcotics, in addition to abolishing fear, made it possible to obtain anaesthesia with a smaller quantity of volatile anaesthetic.

A paper by Dr. R. C. GARRY (Glasgow), on the pharmacological properties of iso-amyl-ethyl barbituric acid (amytal), was read, and subsequently Dr. S. THOMPSON ROWLING (Leeds) read a paper on the administration of anaesthetics.

SECTION OF DERMATOLOGY

Thursday, July 23rd

VARICOSE ULCER

With the President, Dr. H. MACCORMAC, in the chair, Mr. A. DICKSON WRIGHT opened a discussion on varicose ulcer.

He said that the term varicose ulcer was incomplete, and that the disease should properly be called gravitational ulcer, for in all cases the final cause of the ulceration was gravity, and in many cases there were no varicose veins. The essential of all successful treatment of ulceration of the leg was constant support. In practice the treatment must be such as not to involve hospitalization; it must

also be simple, and within the reach of all medical practitioners, and not too laborious and time-consuming. The treatment employed by the speaker consisted essentially in supporting the leg by means of a bandage of elastic sticking-plaster, which could not move when once applied, and which adjusted itself to the shrinkage of the leg. The bandage was wound smoothly in a continuous spiral, and was changed only at considerable intervals—at first, perhaps, once in three days, and later, as the case progressed towards recovery, at longer periods. In healing ulcers a single bandage might be allowed to remain *in situ* for a month or even longer. The method was of practically universal application, there being only two contraindications—associated arterial disease and diabetes. The commonest cause of failure in the treatment was looseness of the bandage. The speaker had cured many cases referred to him as failures merely by applying the bandages more tightly. In some cases eczema developed under the adhesive plaster, and occasionally became generalized; but only in two cases had it compelled him to abandon the treatment. Blisters sometimes formed under the bandage, becoming a source of pain and discharge; but he had never had to stop the treatment on this account. Cutting of the bandage into the skin at times produced linear ulceration in very oedematous legs, but could be avoided by placing longitudinal strips of plaster along the leg as splints. Pain was occasionally increased at first by the pressure, and the speaker had found powdered aspirin sprinkled on the floor of the ulcer an excellent local analgesic, which lasted from four to seven days. He then illustrated the treatment by accounts of difficult cases, one of the most dramatic being that of a woman, the mother of nine children, whose ulcer measured 67 square inches, and the girth of whose leg at its upper border was 15 inches. At the end of thirteen weeks' treatment—consisting merely of the application of the elastic sticking-plaster bandages, aided by the implantation of skin grafts from the forearm under the granulations on four occasions—the ulcer was completely epithelialized, and the girth of the leg was reduced from 15 to 12 inches. Mr. Wright summarized his results by saying that, in all, he had cured 525 cases of ulcer of a total area of 25 square feet. The largest single ulcer he had treated successfully had been one of 180 square inches. He then showed a most interesting cinematograph film illustrating his methods of bandaging, skin grafting, injecting varicose veins, etc., and also many patients before and after treatment.

Dr. TWISTON DAVIES (Brighton) said that he had employed Mr. Dickson Wright's methods in the treatment of ninety-eight cases of ulceration of the legs. Among these fifty-one had healed after an average of 6.3 attendances, eleven had been referred to their own doctor, three had relapsed, five had been lost sight of, and seventeen were still attending. He admitted four failures, in each of which exceptional factors were at work. As regards dermatitis, he had never seen a case which had not yielded to a second and tighter application of elastoplast; and, moreover, he used elastoplast a great deal in the treatment of chronic eczema. He had also used it with some success in Bazin's disease, but with none in "silk stocking" disease. When he had succeeded in getting the ulcer to heal he considered the necessity for permanent support of the leg by measuring the amount it swelled during one week without any bandaging at all. He had had some difficulty in getting the implanted grafts to remain *in situ*, but had now overcome this by anchoring them by means of a knot in a piece of catgut drawn through them. Dr. HALLAM (Sheffield) said that he would rather be Mr. Dickson Wright than have written Gray's *Elegy*. He condemned the common error of thinking that all, or almost all, ulcers of the leg were syphilitic. Dr. INGRAM (Leeds) congratulated Mr. Dickson Wright, and said that he had found that small ulcers were the most difficult to treat. Dr. SEMON said that he had found the interposition of silver foil between the ulcer and the bandage very useful in the promotion of healing in cases which hung fire. Dr. SUMMERHAYES (Brighton) remarked that the use of thin metal for this purpose had been practised in India from time immemorial. He also said that he was glad to tell the meeting that elastoplast bandages were now allowed to the panel practitioner. Dr. HALDIN-DAVIS said that, although Mr. Dickson Wright had revolutionized the treatment of varicose ulcer, in his experience the incidence of eczema was the chief objection to the use of the elastic adhesive bandages. Several other members asked Mr. Dickson Wright questions, to which he briefly replied.

Subsequently short papers were read by Dr. BEATTY (Cardiff), on some points in the treatment of psoriasis; by Dr. INGRAM (Leeds), on the treatment of ringworm of the scalp by thallium acetate; and by Dr. SEMON, on the toxicology of salvarsan compounds.

SECTION OF ORTHOPAEDICS

Thursday, July 23rd

TRANSPLANTATION OF BONE

With the President of the Section in the chair, Professor W. E. GALLIE (Toronto) opened the discussion by remarking that though bone transplantation had proved to be one of the most spectacular and important additions to surgery within the last thirty years, yet the development of a perfect technique had been slow, and failures and disasters were still frequent. Among the causes of failure infection was the most important, since it not only usually caused failure of the graft to unite to its bed, but also introduced the complication of septic necrosis. Great differences in operative technique were found in different centres. Dr. Gallie himself used the Lane technique in all its details. Albee, on the other hand, depended on rapid and skilful performance of the operation. Certainly the Lane technique, unless skilfully used, only complicated and prolonged the operation. Professor Gallie pointed out that a piece of bone, unlike transplanted skin and fascia, died and ultimately underwent complete absorption in its new bed. Lantern slides were shown to demonstrate the death and disappearance of cells from the lacunae, except those in open mouths of Haversian canals, which used such lymph as was available. These latter must not be injured—for example, by burning with a hot saw—and any technique must protect the endosteal surface and subperiosteal cells. New capillaries growing into open Haversian canals, osteoblasts making excavations in the dead graft, and later plastering the walls of the cavities with new bone, the absorption of the whole graft, and replacement by new cancellous bone, were illustrated by slides. Success depended on primary union, the firm healing of the graft to fragments, and finally of the fragments to one another. An analysis of failures showed that the commonest defect was not securing contact of the graft to the bed over a sufficient area; in the radius or ulna it should be embedded 1½ inches into each fragment; in the tibia 2½ inches each. Secondly, insufficiently close apposition of graft to fragments, even such a gap as 1/8 inch, would cause non-union, so that a fair degree of craftsmanship was essential. Insufficient immobilization was a third cause of failure, and not only should an external splint, like plaster, be used, but also internal fixation, such as by boiled-beef pins, or even metal plates and screws. Fourthly, the graft should not be laid into an avascular bed of sclerosed ivory bone. The fragments must be thoroughly opened up. Further, the technique must vary with the problem presented, and

the same plan must not be forced on all cases; but the mechanical details should be settled after the field of operation had been exposed. An adequate incision was essential, but the periosteum should not be stripped further than necessary from the bone ends. For slender bones like the clavicle, Professor Gallie advised the diamond-shaped graft, sprung into its bed, and further secured with thin beef-bone pins, the technique being demonstrated by lantern slides. The medullary peg was condemned, for it acted too often as a complete plug, preventing the outflow of osteogenetic tissue. The inlay graft was advised for big bones like the tibia; it had to be preceded by restoration of the alignment and proper apposition, which might need to be maintained by screws or plates. The graft must contain sufficient living elements, it must be strong enough to act as a temporary splint, and it must resist disintegration until sufficient new bone had been laid down to prevent its collapse. To attain these ends its endosteum and subperiosteal cells were essential, but its actual periosteum could be left behind and sutured over the gap. Experiments had shown that loose-textured bone, like ribs, resulted in most active proliferation of osteoblasts, but such a graft fractured readily if subjected to strain. A sliding graft, when available, was preferable. The mandible was a region where a rib graft gave an excellent result; the method was illustrated by lantern slides. Special instruments were demonstrated for drilling and tapping; it was advised that the hole in the inlay graft should be made loose, so as to get tension when the peg was screwed into the bed. The speaker strongly advised shortening a bone to get end-to-end union, rather than to attempt to bridge a wide gap, unless unavoidable. When this was essential he used the diamond graft, with multiple slivers and crushed cancellous bone. Finally, he urged that if all the above principles were strictly observed in bone-grafting, failures should be extremely rare.

A discussion followed in which Sir Robert Jones and the other speakers congratulated Professor Gallie on his convincing and vivid presentation of both the experimental and clinical sides of the subject. Mr. Elmslie agreed that it would take a bold man to criticize the principles laid down, and the demonstration had been most convincing. With regard to the death of the graft he quoted cases which suggested that its proximal end was revivified extremely rapidly. He had found it easy to bridge gaps in the tibia left by old osteomyelitis, but those from ununited fractures were most difficult. With this last remark Mr. Platt agreed. He inquired whether Professor Gallie resorted to the two-stage operation, so frequently used for war cases—preliminary excision of scar tissue. He did not agree that it was wise to shorten the lower limb much. Mr. A. S. Blundell Bankart commented on the fact that terminal grafts seemed to unite well, though bridge ones were said not to do so. Sir William Wheeler (Dublin) agreed with Mr. Bankart. He also quoted cases showing the amazing way some grafts would survive in the presence of sepsis. Mr. A. Mitchell (Aberdeen) asked what was the best type of graft to fuse the sacro-iliac joint, and Mr. Rowley Bristow asked a similar question in regard to the fusion of tuberculous hips. Professor Gallie replied that he preferred to use a massive graft from the posterior end of the ilium to fuse both lumbo-sacral and sacro-iliac joints at once in view of the difficulties of local diagnosis. In regard to tuberculous hips, he was loath to cut into tuberculous tissues for fear of meningitis supervening.

Adolescent Coxa Vara

Mr. G. Perkins contributed an interesting review of his own method of dealing with cases of what was practically spontaneous separation of the upper femoral epiphysis, as they followed very slight trauma or strain, and the separation occurred exactly at the epiphyseal line, not—as with the real traumatic type—partly through the diaphysis. Mr. Perkins classified the cases as: (1) slight, which were difficult to diagnose, even with *x* rays, and which gave satisfactory end-results apart from any particular treatment; (2) incomplete, repeated, which he said could not be reduced, but should be relieved of weight-bearing till *x* rays showed consolidation of the bone; (3) complete, rapid, which needed reduction, best done by a gradual method—skeletal traction up to 20 lb.; (4) cases resulting in coxa vara in their late stages—in these the arc of hip range was abnormal, at the expense of the internal rotation and abduction; this could be much improved by subtrochanteric osteotomy; (5) arthritic cases, some resulting from too forcible attempts at reduction; these were best treated by arthrodesis.

SECTION OF HYDROLOGY AND CLIMATOLOGY

Thursday, July 23rd

Seaside Treatment of Delicate Children

With the President, Dr. R. Fortescue Fox, in the chair, Dr. Carl Häberlin (Wyk auf Föhr) read a paper on the treatment of children at the seaside (excluding surgical tuberculosis). He pointed out the fact that it was an Englishman, Russel, who "invented" the sea, from a therapeutic point of view, in 1750, and that in England there was still more therapeutic scope than in most countries, owing to an island situation and the differences in climate to be found on the five coasts of Britain. He enumerated the essential qualities which all marine coasts had in common, and dealt at some length with the clinical indications for and against treatment at the seaside, both in hospitals and elsewhere. He stressed as the major indication "the catarrhal child," who reacted well to physical stimuli, and remarked that prolonged treatment was in most cases essential. He pointed out also that the major improvement noticed after successful treatment resolved itself physiologically, largely, into an improvement of the heat-regulating mechanism of the skin, and quoted many ingenious experiments and figures proving this statement. The enormous increase in the basal metabolism of these children was commented upon, and discussed in relation to the iodine content of the air, soil, and food. The dangers of treatment in unsuitable cases was emphasized in relation to the various pathological states for which such treatment was sometimes advised. In dealing with the technique of treatment, he said that the body must be acclimatized gradually, and the result of the various stimuli noted prior to increasing their intensity; otherwise nothing but harm would result.

Dr. Percy Lewis (Folkestone) said that certain principles stood out. (1) The fundamental effects of seaside cures were on the whole body, not on particular organs. (2) The best results of seaside air could only be got on the beach. (3) Skin reaction was important in the cure. (4) Catarrhs did better at the sea in winter than in summer. (5) Delicate children differed immensely, and so did seaside climates. The common features of all seaside climates were abundance of light, a pure, warm, moist, saline air, an equable temperature, and a dense atmosphere with frequent small barometric differences. All these phenomena stimulated metabolism, and were therefore bracing—some more so than others. The abuse of the seaside consisted in sudden change of habits, too brief visits, too long an exposure to sun, air, and sea, and over-excitement. These were all avoided by schools on the coast, which were probably, therefore, the best therapeutic institutions. With precautions, cures at the seaside could not be replaced by anything of equal worth.

Sir HENRY GAUVAIN stressed the need for a seaside hospital to be actually on the sea, and showed many interesting lantern slides illustrating the technique of seaside therapy. After having discussed at some length the types and conditions of patient suitable for this kind of treatment, he gave interesting data and figures in support of his views. He briefly reviewed the architecture of seaside hospitals, pointing out that it was the walls and roofs of the hospital which should be moved to meet differing climatic conditions, and not the patients themselves if bed-ridden. Dr. W. S. C. COPEMAN gave the results of a questionary sent out to medical men and institutions on all the coasts of Great Britain, summarizing their views and usage with regard to the choice of cases for their locality, and the differences noticed at various seasons. Their observations on malnutrition, catarrhal conditions, rheumatic and cardiac cases, and nervous instability (including chorea), and use of physical medicine on the coast by medical authorities, were all considered. Dr. HUGH RAVEN (Broadstairs) also read a detailed report on the same questions undertaken by him, with the help of twenty colleagues in the Isle of Thanet. Dr. COLLIS HALLOWES (Torquay) and Dr. STOTT (M.O.H., East Sussex) spoke on the same subject.

Dr. FORTESCUE FOX, President of the Section, after thanking the preceding speakers, and emphasizing the need for further detailed investigation on similar lines, moved a resolution to the effect that the Section considered the time ripe for the formation of an association of marine practitioners and others for the scientific development of these forms of treatment in the British Isles. This was seconded by Dr. PERCY LEWIS (Folkestone).

RURAL HYGIENE

CONFERENCE AT GENEVA

The Conference on Rural Hygiene, held at Geneva last month, under the presidency of Professor GUSTAVO PITTALUGA (Spain), was summoned by the council of the League of Nations on the proposal of the Spanish Government. Its object was an international technical study of rural hygiene, as one of the most important factors in the organization of European agricultural regions. Inquiries by experts into the present health organization of various European countries formed the basis of this study, and a special preparatory committee drew up an agenda (adopted by the conference), which included the following points for consideration: (*a*) guiding principles and appropriate methods for ensuring effectual medical care in rural communes; (*b*) the most effective methods of organizing health services in rural districts; (*c*) the "amelioration" of rural dictricts—most effective and most economical methods. Three committees were appointed to consider these three questions, and a fourth was instructed to decide which of the suggestions put forward by delegates could be studied by a future conference or by the League Health Organization.

The first committee decided that medical assistance should include both preventive and curative methods, and proposed means for making it efficacious, laying special emphasis on health insurance and on the need for close co-operation between administrative and technical services. It then discussed the question of the sanitary staff providing such assistance, as well as the administrative and technical conditions that must be fulfilled. The second committee considered the two main forms of health organization: the administration of local sanitary services by the State (the State's functions being purely supervisory), and sanitary administration under the responsibility of local authorities. Special attention was devoted to the question of rural health centres. The third committee dealt with questions of water supply, housing, the elimination of waste products, and with amelioration of rural districts. The reports of the three committees were unanimously adopted by the conference.

The programme drawn up by the fourth committee for study by health institutes included: (*a*) schools for health visitors; (*b*) training of sanitary officers; (*c*) cost of health and rural medical services; (*d*) rural improvement; (*e*) housing in rural districts; (*f*) rapid transport of sick in rural districts; (*g*) close co-operation between public assistance administrators, architects, agriculturists, hygienists, etc.

Directors of schools of health who met during the conference prepared the following list of problems for study by their schools: (1) milk in rural districts; (2) typhoid notification; (3) use of manure and anti-fly campaign; (4) cost of sanitary equipment; (5) methods of analysis and testing, and the methods of testing the water supply and of waste products used in various countries. Professor MIYAJIMA (Japan) stressed the importance of the results obtained for non-European States, and the desire of those countries to benefit by them as regards the development of their own national organizations.

In his closing speech the president, M. PITTALUGA, applauded the cordial spirit of international co-operation shown by the members of the conference, expressing the hope that the delegates, on their return home, would submit the recommendations of the conference to their Governments. "I am sure," he said, "that the conference marks a great step forward in the organization of medical assistance in rural districts. For the first time hygienists, engineers, agriculturists, and administrators have come together to discuss the question of the organization of rural life and the welfare of rural populations."

ROYAL MEDICAL BENEVOLENT FUND

Subscriptions and donations are urgently needed in order that the activities of the Fund may be continued. Cheques should be forwarded to the Honorary Treasurer, Royal Medical Benevolent Fund, 11, Chandos Street, Cavendish Square, London, W.1. At the last meeting of the committee twenty-nine grants were voted, amounting to £689 10s. The following are particulars of a few of the cases helped.

Widow of M.B., Ch.B., who died last March at the age of 37, leaving her only a capital sum of £600 and an infant 3 years old. A medical man, in recommending this case, wrote: "The husband was the most distinguished medical graduate of his year. After graduating with honours he settled in what seemed fair to be a lucrative practice in one of the newest and rapidly expanding suburbs, but his scientific bent caused him to make the sacrifice of giving up his practice in order to devote himself to the study of scientific pathology. His early death has left his widow with inadequate means of support for herself and her young child. I can think of no case which more deserves the sympathetic consideration and support of the committee." Voted £30. Personal touch with the applicant will be maintained, and further help or advice will be given if possible.

M.R.C.S., L.R.C.P., aged 74, widower. The honorary local secretary of the Fund, in recommending the applicant, wrote: "For several years he has suffered from paralysis agitans, and is very feeble and helpless." The applicant himself writes: "I have been unable to attend to my patients, and many have fallen off. I am quite unable to do anything for myself, and have to employ a male attendant to dress and undress me and to attend to me during the night, and I also require assistance to move about the house." Assured private income £68; friends give some help. Voted £40.

M.B., B.Ch., aged 40, with wife aged 31 and a daughter aged 10. Applicant has had to give up practice, and is in hospital with sarcoma in the hip. Wife and child are living on proceeds of sale of the practice, thereby using up the only capital. Voted £40.

Widow, aged 73, of L.R.C.P., who died at the age of 75 in March last. Her only income is the old age pension of £26. Voted £26.

The Royal Medical Benevolent Fund Guild still receives many applications for clothing, especially for coats and skirts for ladies and girls holding secretarial posts, and suits for working boys. The Guild appeals for second-hand clothes and household articles. The gifts should be sent to the Secretary of the Guild, Tavistock House (North), Tavistock Square, W.C.1.

FOREIGN MEDICAL PRACTITIONERS IN CHINA

The Minister of Health has received officially the following particulars with regard to the arrangements governing the granting of certificates to foreign medical practitioners wishing to practise in China.

1. Foreign doctors, when applying for certificates as medical practitioners, must first forward their examination diploma and any other documents attesting their qualifications to the nearest consul of their nationality for his inspection, with a request that he issue a certificate.

2. When the consular certificate has been obtained, it should be forwarded, together with a statement of the applicant's record, two 2-inch half-figure photographs, a registration fee of five dollars, and a stamp tax fee of two dollars, to the appropriate local government department (that is, the health bureau; or, if the district has no health bureau, then the public safety bureau or the district government), for transmission through the proper authorities to the Health Section of the Ministry of the Interior for consideration with a view to the issue of a certificate.

Ireland

Professor Thomas Sinclair

A fund is being inaugurated in order that the friends, colleagues, and pupils of Colonel Thomas Sinclair, M.D., F.R.C.S., Emeritus Professor of Surgery in Queen's University, Belfast, may have an opportunity to express their appreciation of his invaluable services to the Belfast Medical School. Professor Sinclair occupied the chair of surgery from 1886 to 1923; he served as a consulting surgeon with the Army Medical Services in France and Egypt during the great war, and has represented the Queen's University in the Imperial Parliament since 1923, in addition to being its registrar and pro-chancellor. He is also a member of senate in the Parliament of Northern Ireland. The testimonial will probably take the form of a portrait to be painted and presented to the university. Subscriptions, limited to £2 2s., may be sent to the honorary treasurer, the Right Hon. Samuel Cunningham, P.C., 3, Donegall Square East, Belfast.

The Rotunda Hospital

The annual report of the Rotunda Hospital for the twelve months ending October 31st, 1930, is, as usual, a compilation of information of great interest to gynaecologists and obstetricians. The amount of tabular information has been slightly reduced in this issue by abbreviating the statistics relating to uterine inertia, but, otherwise, the present volume follows the same lines as its predecessors. The outstanding event of the year under review was the opening of an extension of the gynaecological department. This has brought into being an additional operation suite. The new theatre is ventilated by warm air supplied from a chamber on the roof; vitiated air is removed by ducts near the floor. This method has proved successful in practice, and it obviates the necessity for radiators, which collect dust, and are difficult to keep clean. The number of admissions to the maternity side of the hospital was 2,789; of these, 2,258 patients were delivered. This represents a definite increase in admissions, and indicates the considerable number of cases available for illustrating pre-natal teaching. The hospital was also responsible for 1,724 deliveries in the patients' own homes. There were no deaths in the in-patient department, but this was to some extent due to external that cases requiring careful watching and nursing the fact were admitted at once to the hospital. Dr. Bethel Solomons, Master of the Rotunda, comments on the large number of women, apart from those suffering from eclampsia or eclampsism, who were found to have albuminuria on admission. In view of the regular persistence of this finding in successive years, he is inclined to suggest that albuminuria may sometimes have to be considered a normal occurrence in pregnancy. There were thirty-seven cases of eclampsia, and three patients died; none of the eclamptics had had pre-natal care. Nineteen cases of placenta praevia were dealt with, and there was no maternal mortality; the foetal mortality rate was less than previously. Only three Caesarean sections were performed, and Dr. Bethel Solomons maintains his belief that bipolar version is the best treatment to teach in this condition, since it is more generally applicable. The total number of Caesarean sections performed in the hospital during the year was forty-three, and there was also one Caesarean hysterectomy. In his pathological report—which is included as an appendix—Dr. F. S. Bourke mentions an attempt to investigate a possible source of haemolytic streptococci, a series of throat cultures being made from swabs taken from the nursing, post-graduate and student staffs, with special attention to those persons working in the theatre. A few primary cultures of haemolytic streptococci were obtained, but these on sub culture were found to be no longer haemolytic. Some of the swabs were taken from persons suffering from sore throat, and not on duty, but in no instance were any genuinely haemolytic streptococci recovered. Dr. Bourke also refers to the difficulty of obtaining suitable donors for blood transfusion. He adds that it is no longer the practice to depend on the results of typing with the group serums, since one or two alarming experiences have resulted. It is now customary to perform a cross-typing with cells and serum from the patient and the prospective donor. This takes up rather more time, but the after results have justified confidence in the method.

England and Wales

Medical Charity in Yorkshire

The hundred and third annual meeting of the Medical Charitable Society for the West Riding of the County of York was held at Bradford, on July 23rd, under the chairmanship of Dr. David Walker. The Lord Mayor of Bradford, by whose courtesy the meeting was held in the City Council Chambers, was present at the opening of the proceedings, and made some appreciative remarks on the work of the society, which continues to increase. During the year grants amounting to £2,006 were made in response to thirty-nine applications, the total amount given by the society in grants up to June 30th being £85,134. Losses to the society by deaths, resignation and other causes were more than made up by the election of thirty-five new members, and the year begins with a total membership of 1,099. The growth of the society is indicated by the fact that during the decennial period 1921–30 the number of members increased from 862 to 1,089. In regard to the financial position it is gratifying to find that though the grants have amounted to the large sum mentioned above, the investments standing in the name of the trustees, with a nominal value of £49,996, have been bought at a cost of £42,986. The work of the society is carried out by a treasurer, secretary, and stewards, and beyond the cost of printing, postage, the actuary's fee, and a small commission to the bankers as trustees, there are no expenses. This year a legacy of £500 has been received under the will of the late Mrs. M. A. Major in memory of her husband, Dr. Herbert Coddington Major, formerly of the West Riding Asylum. The objects of the society are to help: (*a*) any member who is disabled by illness or age, and who has not adequate means of support; (*b*) the widow or children of a member dying in indigent circumstances; (*c*) the mother of such

a member, being a widow (or the sister, being single or a widow), who has acted as his housekeeper for a period of not less than five years immediately preceding his incapacity or death, and (*d*) in the education of the children of disabled members. Any regular medical practitioner residing in the West Riding of the County of York, in good health, may be proposed as a member of the society, provided he is under 40 years of age, and has not been in practice in the West Riding for more than fifteen years without being a subscriber. A member who leaves the Riding or the country may continue his membership and enjoy all its privileges.

New Admission Villa at Hanwell Mental Hospital

The centenary of Hanwell Mental Hospital was celebrated on July 29th by the opening of an admission hospital villa. In the absence of the Minister of Health, the ceremony of opening was performed by Mr. L. G. Brock, chairman of the Board of Control. Mr. Ernest Sanger, chairman of the London County Council, presided. The admission villa is a detached self contained unit for the reception of all new cases, of both sexes, and embodies special facilities for close observation and careful treatment on distinctively hospital lines. To encourage the atmosphere of hopefulness and to approximate the institution to a hospital for physical sickness, women nurses mainly are to be employed. The accommodation provided is for fifty male and fifty female patients, and on each side there are examination rooms, sick dormitories, verandas, and a solarium, while in a central position there is an association room for the use of both sexes. Special rooms for *x* ray and light treatment and Plombieres baths have also been provided.

After Dr. Adeline Roberts, chairman of the Mental Hospitals Committee of the London County Council, had explained what it was hoped to do in the villa, Mr. Brock gave an address, in the course of which he reminded the gathering that Hanwell was the oldest public mental hospital in London, and about the fifth in priority in the country. It had great traditions. Its first superintendent, Dr. (afterwards Sir William) Ellis, brought with him the idea which took shape in the Queen Adelaide Fund, which was really the germ of the whole after care movement. That movement, said Mr. Brock, was going to develop in the near future, and, he believed, would prove a most potent ally of the modern mental hospital. The admission unit Mr. Brock regarded as the centre of the whole organization, and he said he could not over emphasize its importance. Many people did lip service to the idea of early treatment without acknowledging that obviously it included two things—namely, earliness and treatment. They were often content to provide places where the new admissions could be kept separate from the rest of the hospital, and to do no more. It was true that admission units were places where those newly admitted could be kept out of contact with chronic patients, but that was only to solve half the problem. The patient had not only to be placed in suitable surroundings, but everything possible had to be done to improve his condition. There was room for controversy as to the value of different therapeutic methods, but no shadow of doubt as to the importance of making the patient feel that everything possible was done for him. It was of no use calling institutions hospitals unless that psychological factor was appreciated. The recovery rate in mental cases, said Mr. Brock, had remained stationary during the last generation. It was not a bad rate, though not so good as it ought to be, and he was confident that before long the concentration of effort now being made and the multiplication of admission hospitals would result in a marked improvement in the figures. There was no justification for the pessimistic attitude which refused to try new things owing to the supposed hopelessness of mental conditions, that point of view was contradicted by the results forthcoming in the induced malarial treatment of general paralysis. The scheme of improvement at Hanwell includes a nurses' hostel, and Mr. Brock, in conclusion, paid a high tribute to mental hospital nurses. He had now visited, he said, nearly all the public mental hospitals in the country, and everywhere he was struck by nursing devotion. He had seen good hospitals, hospitals that were less good, and a few that were frankly bad, but they all had this feature in common, that the patience, forbearance, and kindliness of the nurses was beyond praise. No occupation was more exacting than theirs, and when he thought of the physical and moral strain of attendance in the wards hour after hour, he wondered that so many could be found to undertake it.

The visitors afterwards inspected some of the records and relics of the early days of Hanwell, including the apparatus once used for mechanical restraint. The hand cuffs, muffs, and leg locks were certainly barbarous, yet Hanwell in the hundred years of its history has been a pioneer in the humane treatment of the insane. John Conolly, who became its superintendent in 1839, inaugurated restraint free methods, in the face of considerable objection from his subordinates and others. William Ellis also, an earlier superintendent, saw so far ahead as to introduce occupation therapy. In 1889 the London County Council became responsible for the government of the hospital. During the forty two years which have elapsed since then, Hanwell has had only three medical superintendents.

The Waking Hour in Hospital

The Minister of Health has issued a memorandum to all county and county borough councils in England and Wales, drawing attention to the report on patients' waking hours in London voluntary hospitals, published by King Edward's Hospital Fund for London,[1] and suggesting that the councils will no doubt wish to consider the question of adopting the recommendations in the administration of their own hospitals. The principal recommendations in the report are that, unless there is some exceptional and adequate reason to the contrary, the most suitable hour for the waking of patients is 6 o'clock, and that, whatever the official hour may be, no patient should be washed before having either breakfast or early morning tea. At the annual meeting of the council of King Edward's Fund the Prince of Wales made the following reference to the report: "The subject has been talked about for years, and the difficulties are well known to all hospital people. A few hospitals have been making experiments. They have certainly brought the question to the front, as is shown by the fact that it was taken up last year, almost simultaneously and quite independently, by three different bodies, each in its own sphere—the British Hospitals Association, the London County Council, and the King's Fund—and the three reports all point more or less to the same conclusion."

Mental Patients in the Care of the L.C.C.

The total number of persons of unsound mind for whom the London County Council was responsible on January 1st last was 25,819, an increase of 208 on the year. Of this number, 21,053 were in the county mental hospitals. In addition, the Council was providing accommodation in one of the institutions transferred from the Metropolitan Asylums Board for 912 aged patients without formal reception orders. The number of persons accommodated in institutions provided for the mentally defective under the Mental Deficiency Acts was 3,372, and in addition, at a training colony, there were 782 feeble minded persons who were not the subjects of reception orders.

[1] *British Medical Journal*, 1931, i, 52.

Scotland

Royal Victoria Hospital and Sanatorium Colony

In the last annual report of the Royal Victoria Hospital Tuberculosis Trust reference is made to the erroneous view sometimes put forward that the incidence of tuberculosis is automatically decreasing. While the mortality rates from this cause in London, Edinburgh, and New York have fallen remarkably, the figures in other capital cities, such as Paris, Warsaw, and Vienna, continue very high. The conclusion is inevitable that good results only follow continued and well-directed effort. In view of the belief that this infection is generally contracted in childhood, and that treatment at that age has a most important bearing on later life, special efforts have been made by the Trust with the object of detecting and dealing with juvenile patients. The number of these admitted to the sanatorium colony at Southfield has grown steadily, and now a new pavilion to accommodate twenty or thirty children is being erected there; it consists of a one-storied block, the wards of which open directly on to a raised terrace, and a considerable part of the flat roof of the pavilion will be adapted for treatment. This addition will greatly increase the opportunities of developing further measures of anticipatory detuberculization. Work has proceeded on the prognostic value of the blood sedimentation test and the leucocyte reaction to tuberculosis from the point of view of prognosis, and laboratory observations have been continued in regard to the communicability of human infection to cattle. The committee appeals for a sufficient endowment to ensure an annual expenditure on research of £600 to £800 for the next five years. In a reference to the Lübeck tragedy caution is expressed as to the advisability of sanctioning the use of B.C.G. vaccine on the wide scale which has been adopted in some countries, because time alone can reveal the extent and duration of the protection, and define the degree of risk involved.

Animal Diseases

At the annual meeting of contributors to the Moredun Institute of the Animal Diseases Research Association, the president, Mr. Falconer L. Wallace, stated that its research staff had been augmented, and that a biochemical department had been established in a suite of laboratories provided by the Royal (Dick) Veterinary College. As work was being carried on in collaboration with the Rowett Institute and with the Macaulay Institute, the various research institutes in Scotland were co-operating as a team. In reviewing the results of last year Dr. J. Russell Greig said that definite progress had been made. The disease known as "louping-ill" had been a problem for the past century, and the Moredun Institute had now determined that the cause of this disease was an ultra-microscopic filterable virus, and, further, it had been able to show that a very efficient immunity could be set up by inoculating this virus into healthy sheep. It was now attempting to obtain a method of immunization which would be both safe and efficacious, and for this purpose field experiments on a large scale were being carried out. There was evidence that under natural conditions this disease was transmitted by a tick. Preventive vaccine had been prepared from the lamb dysentery bacillus in large quantities, and approximately 38,000 doses had been distributed to flock masters in the past year. From tuberculin tests obtained in combating this disease alone, all the money expended by the Animal Diseases Research Association since its inception had been returned to the farmers in whom infection had been eradicated. Dr. Greig remarked that grass sickness was still one of the most baffling problems of veterinary science, but this offered a promising subject for investigation to be carried out next season.

Queen's Institute of Nursing

At the quarterly meeting of the Scottish council of the Queen's Institute of District Nursing, H.R.H. the Duchess of York presented long-service badges to three Queen's nurses who had served twenty-one years in the Institute. The report showed an increase in revenue during the quarter as compared with that of the corresponding period in the previous year. In regard to the prevention of tuberculosis, reference was made to the work that had been done by the nurses of the Institute in collaboration with the National Association for the Prevention of Tuberculosis, the Royal Victoria Hospital Tuberculosis Trust, and the Scottish Branch of the British Red Cross Society. This work has been carried on for the past two years in Inverness-shire and Ross-shire, and will shortly be extended to the Orkney and Shetland Islands. During the quarter twenty-one nurses who had completed district and midwifery training were placed in first appointments. The report also mentions that 146 nurses were employed in 108 different districts, which were inspected from the Institute headquarters. In Edinburgh the nurses under training attended 1,164 patients, upon whom they paid a total of 44,943 visits.

India

Medical Aid for Women and Children

As in recent years a single volume has been published comprising the reports for 1930 of three separate organizations, then under the presidency of Lady Irwin—namely, the National Association for Supplying Medical Aid by Women to the Women of India (Countess of Dufferin's Fund, including the Women's Medical Service), the Victoria Memorial Scholarships Fund, and the Lady Chelmsford All-India League for Maternity and Child Welfare. It is announced, however, that the League has been dissolved as from December 31st, 1930, and that its property is being transferred to the Indian Red Cross Society after all the debts and liabilities have been met; that organization will thus include henceforth the National Baby Week Council, which was originally part of the Lady Chelmsford League. This marks a further step in co-ordinating the activities of the various bodies engaged in maternity and child welfare in India. It is fitting that the Red Cross Society should have a greater power of control, since it is the strongest organization concerned, spending considerably more of its income on child welfare work than do the others. As a corollary to this decision the governing body of the Countess of Dufferin's Fund has decided to transfer the control of the Victoria Memorial Scholarships Fund to the Indian Red Cross Society; this Scholarships Fund will continue to be administered in accordance with the objects defined at its inauguration in 1903 by the late Lady Curzon. It is mentioned in the joint report that the managing body of the Indian Red Cross Society has now set up a Child Welfare Bureau with effect from the beginning of 1931. Progress has been very slow also as regards the training of native midwives by health visitors, partly owing to the fact that the teachers have so far not developed any marked enthusiasm for this rather tedious branch of their work. The difficulty of supervising midwives after they have been trained has proved insuperable up to the present, again owing to the shortage of staff. Rural areas are still largely untouched, the trained midwife preferring to work in towns. Now that these difficulties have been

openly discussed at various conferences it is hoped that more energetic measures may be devised for instructing midwives, not only as regards the care of parturition, but also in ante-natal work. The main body of the joint report comprises detailed accounts of the work that is being carried on in various hospitals for women and children.

Bengal Hospitals and Dispensaries

In his triennial report on the working of hospitals and dispensaries under the Government of Bengal for the years 1926–28 inclusive, Major-General G. Tate, I.M.S., Surgeon-General to that Government, states that these three years have been particularly difficult for those in administrative charge of the larger medical institutions. In 1927 serious handicaps of staffing and managing hospitals in Bengal were brought to light, but the recommendations of the Lee Commission, which reduced the appointments reserved for I.M.S. officers, have resulted in the retirement and transference of several experienced officers, with consequent further damage to the Service. In an effort to comply with the recommendations of the General Medical Council changes have been made in the curriculum of the University of Calcutta; and additional equipment has been obtained. Great difficulties still continue to exist in obtaining qualified medical officers for rural areas where there are few social amenities, indifferent educational facilities for children, and a very doubtful prospect of making a living. The Calcutta School of Tropical Medicine and Hygiene is increasing each year its popularity and usefulness; post-graduate training has been intensified, and an out-patient department has now been opened. The chief researches conducted under the auspices of the Indian Research Fund Association include an inquiry into the mode of transmission of kala-azar, probably by the sandfly; the study of filariasis; and the investigation of the treatment of leprosy by the ethyl esters. Increased facilities have been provided in Calcutta for the treatment of venereal disease. The total number of operations performed in all classes of Calcutta hospitals during the period under review was 158,000, as compared with 129,000 in the preceding triennium.

School Medical Examinations in Agra and Oudh

In October, 1929, an important change was made in the system of medical inspection of schoolboys in the United Provinces of Agra and Oudh. With the concurrence of the public health and education departments it was arranged that the medical inspection of scholars in the Government and aided English schools should be conducted, whenever possible, by district and municipal medical officers of health who had been nominated by the Director of Public Health. Before this date the practice had been for such examinations to be made by members of the Provincial and Subordinate Medical Services. In the case of boys living in hostels attached to schools the school medical officer treats and prescribes for them as before, while the new school health officer is responsible for the general health of all the boys at the school, whether resident in the hostels or not, and arranges for periodical medical inspections. In his annual report for the year ending March 31st, 1930, Lieut.-Colonel W. A. Mearns, I.M.S., Officiating Director of Health for the United Provinces, states that the new scheme is now in operation in the English schools, and in the intermediate colleges for boys, in forty-four towns. Once a year the boys are examined in detail for various defects, and monthly parades are held, when the condition of their eyes and teeth, and their general cleanliness, are noted. Municipal officers of health examine the boys in the vernacular schools, but, in view of the very large number concerned, it has not been possible to adopt so complete a scheme of inspection; there is one detailed examination each year, but monthly examinations are not held. Colonel Mearns remarks that there is still room for improvement in the medical records thus obtained from some places, but he indicates one useful side of this scheme in mentioning the fact that such local authorities as the chairmen of district boards, the district inspectors of schools, and the local magistrates receive copies of the reports, and can therefore take action when any general cause of ill-health is brought to light. As elsewhere, difficulty has been experienced in persuading the parents of defective boys to take steps to secure treatment, even when ample facilities exist locally. In the rural areas the medical officers provide any necessary drugs at the time of their examinations. Figures are given of the meagre attendances at dispensaries and clinics of these defective children, even when all arrangements have been made for them, and it is concluded that a strong case exists for the establishment of school clinics, so that the boys can be dealt with in their own schools. Hygiene is now taught once a week in certain classes of the English schools in towns, and in nearly all the village schools. Proposals are being considered for ranking hygiene as a compulsory subject in the school curriculum, with periodical examinations as in the case of other compulsory subjects. Medical officers of health are now investigating the sanitation of school premises, hostels, water supply, the adequacy of lighting and ventilation, and also the suitability of the school furniture to individual needs. The school educational authorities are co-operating well.

Ophthalmic Work in Madras

In the annual report and statistics of the Government Ophthalmic Hospital, Madras, for 1930, the superintendent, Lieut.-Colonel R. E. Wright, I.M.S., states that increasing use has been made of the Barraquer procedure for cataract, which has proved satisfactory. Escape of the vitreous occurred much less often than in the previous year, but is still considerably more frequent than in the ordinary capsulotomy operation. When the Barraquer operation is successful, excellent results ensue as regards vision, and Colonel Wright believes that further experience of it will indicate lines for wider application. The bridge flap technique, adopted in most cases throughout the year, appears to be associated with a denser after-cataract, probably owing to the greater frequency of haemorrhage into the chamber at the time of operation. The occurrence of shallow chamber at the first dressing (on the third day) appears also to be more common after the bridge operation; this is associated with adhesions of capsular tags to the corneal endothelium, and consequent keratitis. In glaucoma, sclero-corneal trephining has been the operative treatment adopted. Most of the patients admitted with this condition are in an advanced stage, and many require a good deal of preliminary treatment before trephining. The adrenaline pack was often used, together with free administration of eserine. Anterior sclerotomy proved a helpful preliminary measure in cases where the tension remained high in spite of all efforts to reduce it. Superficial punctate keratitis was more common than last year, but it has appreciably altered in its characteristics; the conjunctival condition is more severe than when the disease appeared in epidemic form in 1928, but there is no doubt that the present malady is the same as that previously observed, though now in a more severe form. Gross iritis was never seen, and the severity of the signs was out of all proportion to the symptoms. In the treatment of keratomalacia the use of concentrated vitamin A alone did not appear to be so effective as cod-liver oil. Chaulmoogra oil was employed in a number of cases of trachoma, where it appeared to give considerable relief and to keep the condition stationary. The oil did not injure the cornea, even in ulcerated cases, but it had little, if any, influence on pannus.

THE FACTOR OF INFECTION IN THE RHEUMATIC STATE

SIR,—Permit me to add emphasis to the importance of the subject of your leading article of July 18th (p. 109). Dr. Coburn's monograph[1] demands a patient study, which all interested in rheumatism are in duty bound to give it. It is a complete vindication of the text of Dr. Glover's Milroy Lecture,[2] "restating the incidence of acute rheumatism (notwithstanding its low infectivity) as the incidence of a specific infectious disease conveyed by droplet infection." The "positive etiological environmental factor" which Dr. Savage's valuable interim report[3] has failed to reveal is a widespread streptococcal parasitism.[4] Although this factor is increased by overcrowding and damp, it may be entirely absent even under the worst environmental conditions. On the other hand, it can and does occur in the higher grades of society, provided the conditions conduce to a high carrier rate of certain streptococci. Dr. Reginald Miller is misinformed. Sporadic rheumatism may be rare in public schools, but epidemics of the disease occur in these schools, and have been reported by Glover,[2] Raven,[5] and Haig-Brown,[6] and at least three English public schools have experienced waves of acute rheumatism during the past year.

Following forty years' freedom from acute rheumatism, and a period of at least three years during which haemolytic streptococci were rarely found in occasional throat-swabbing experiments, a haemolytic streptococcus became prevalent in a group of ninety boys at the end of October, 1929. It produced an epidemic of streptococcal sore throat, giving a clinical picture of lacunar tonsillitis in boys with tonsils. Five cases of acute rheumatism followed after a "lag" period. A further group of 250 boys housed in the same building, but partly isolated from the original infection, remained relatively free from sore throat until the next term, when an extensive wave of streptococcal fever invaded it, and produced eleven cases of acute and subacute rheumatism and one case of chorea. In twelve of these seventeen cases repeated "sensitizing attacks" of sore throat were observed before the onset of rheumatism. Five of the patients acquired permanent heart lesions, but were outside the scope of the Bristol inquiry on account of age.—I am, etc.,

Stratton-on-the-Fosse near Bath, July 20th — W. H. BRADLEY.

THE SIGNIFICANCE OF A RAISED BLOOD PRESSURE

SIR,—Dr G. Arbour Stephens has been kind enough to criticize my contribution to the *British Medical Journal* on the significance of a raised blood pressure. To some extent I think his difficulties are due to the fact that he has either misread or misunderstood my remarks.

To begin with, he pillories me for failing to define either systolic or diastolic pressure. This is true; it seemed to me unnecessary, but from the sequel it is clear that I should have done so. I have always understood by systolic arterial pressure the pressure which occurs during ventricular systole, and by diastolic the pressure at the end of the diastole. With the clinical means at our disposal the findings are only approximately correct, but for all practical purposes they serve.

Dr. Stephens asks whether I consider that "diastolic pressure is the same in all the arteries, and if not, why not. Frankly, I do not know. I am unaware of any experimental work dealing with this aspect of the subject, and in any case I question whether such knowledge would be of any clinical value. He also carps at me for making use of the phrase, "high blood pressure may be latent," and suggests that this is misleading. It was used to cover a group of patients in whom a raised blood pressure failed to give rise to any discomfort or distress—patients apparently in good health, and often leading active and vigorous lives—the rise in pressure being discovered during the routine examination for some trifling ailment or for insurance purposes.

On reading Dr. Stephens's letter one cannot escape the conclusion that he would have your readers believe that I consider the technique of recording blood pressure unsatisfactory, and that the records obtained are unreliable. If I might venture to say so, this is a misrepresentation. He bases his opinion on the following quotation: "to take a blood pressure reading is simple enough, but my impression is that *in some instances* [italics mine] the technique is not satisfactory, and the records, especially of the diastolic pressure, are unreliable." I made it quite clear that those instances were the exception, and not the rule, as Dr Stephens infers. Unfamiliarity with, or ignorance of, the correct technique is sometimes met with, and it is *then* that the results are unreliable. I was making a plea for reasonable care in the method of recording blood pressure.

In his last paragraph there is a further example of failure to understand my meaning. Dr. Stephens fathers me with the opinion that the "tendency is to take too high a reading," suggesting that this is due to faulty technique. Again he has misread my statement. What I actually said was: "There has been a tendency to take as normal a reading far too high," a statement with which I am sure Dr. Stephens is in entire agreement.

Dr. N. Pines, writing as an ophthalmologist, emphasizes the importance of retinoscopy in all cases of raised blood pressure, a point of view with which I readily concur. The examination of the retinal vessels must, of course, be part of the routine in the investigation of such patients. But in condensing my address for publication this phase was inadvertently omitted. I wish, however, that I could also agree with Dr. Pines that "sudden vascular accident or death of a hyperpietic is usually the fruit of a deficient medical examination." Such patients, warned or otherwise of the seriousness of their condition, will, I am afraid, always be liable to such catastrophes.—I am, etc.,

Liverpool, July 28th. — JOHN HAY.

SIR,—In his letter in the *Journal* of July 25th, Dr. Arbour Stephens complains that the address by "Professor John Hay in the *Journal* of July 11th has a tendency, by its indefiniteness, to lead one astray." And now Dr. Stephens is doing his best to lead innocent readers astray by talking about *basic blood pressure*. Must we overburden the nomenclature of the disease called hyperpiesis, hyperpiesia, hypertonia, hypertension, high blood pressure, arterio-sclerosis, athero-sclerosis, diffuse hyperplastic sclerosis? Apparently Dr. Stephens means diastolic blood pressure when he uses the term "basic blood pressure." I beg of him, therefore, to desist, and to fall in with the whim of the majority, which still finds comfort in the word "diastolic."—I am, etc.,

TREATMENT OF DYSMENORRHOEA

SIR,—Will you kindly allow me space to reply to the interesting discussion arising out of my paper on the treatment of dysmenorrhoea?

Surely the great divergence of opinion which arises concerning the treatment of this common complaint is due to the fact that it is insufficiently realized that dysmenorrhoea *is a symptom and not a disease. One might* as well offer a specific for headache as try to treat all cases of dysmenorrhoea by the same method. I therefore suggest to Dr. Curtis Webb that we are indeed much further on if we can correctly classify our cases.

The opinion that electrical treatment of some kind is a cure-all for dysmenorrhoea is by no means so unanimous as he would have us suppose, even among medical electricians. Cumberbatch, in *Diathermy* (p. 161), says:

"In a few cases complete and lasting relief is obtained. In others the relief was incomplete, and the continuation of the diathermy did not procure further benefit."

Dr. Sanderson Clow's letters must command our respect, not only because of her own large experience, but also because one feels that she is speaking for the Medical Women's Federation. In all humility I submit that it is a backward trend, both in the principle and the practice of medicine, to treat any symptom without thorough examination, and without due recognition of the cause. I am totally misrepresented as advocating the treatment of dysmenorrhoea by dilatation of the cervix. I do advocate that treatment in the small class of cases where the pain is due to faulty neuro-muscular mechanism combined with conical cervix and pinhole os. In these women the pain is often very severe, and to send them away with a system of exercises is like giving them a stone when they have asked for bread. The great majority of cases, of course, can be placed in my first group of "the psychological type," and these will benefit greatly from exercises and baths.

I wish to thank Dr. A. A. Gemmell for his kindly criticism, and to endeavour to answer the points he has raised. In saying that the uterus is abnormally small in many cases of dysmenorrhoea I was speaking of the uterus and not of its cavity. The point is that the wall of the uterus is more fibrous than usual—at the expense of the musculature. Though the cavity may be normal in length, the wall is thinner, causing the uterus to *feel* abnormally small. In those cases where the uterus is larger than normal I would suggest that, in the absence of pathological change, there is some endocrine disturbance, and that the benefit of dilatation is doubtful. I should have stated that the type of dilator I use is the type I was brought up on—namely, Hegar's.

Lastly, may I repeat that if practitioners will endeavour to classify their cases of dysmenorrhoea into psychological, endocrine, mechanical, and gross pathological, and treat them accordingly, they will not merely benefit their patients, but they will find a new interest in their treatment.—I am, etc.,

Torquay, July 27th. B. VENN DUNN.

CONVULSIONS DURING ETHER ANAESTHESIA

SIR,—As the subject has recently been discussed in your correspondence columns, the following case of ether convulsions may be of interest to anaesthetists.

A woman, aged 39, had had pain in the lower abdomen for ten days. A mass was felt by abdominal and pelvic examination. Temperature 103°, pulse rate 120 on admission. Diagnosis was salpingo-oöphoritis. She was kept under observation for six days, when temperature was 100.6°, pulse rate 112. After a preliminary pelvic examination under anaesthesia had been done, it was decided to open the abdomen forthwith.

Anaesthesia was induced with 10 c.cm. of ethyl chloride on an open mask, and continued with ether. Induction was uneventful. Soon after surgical anaesthesia was established it was noticed that she was slightly cyanosed, and a slow stream of oxygen was given continuously through a Hewitt's air-way. The colour immediately improved and was satisfactory till the fits began. Anaesthesia was deepened when the laparotomy was begun by Professor F. J. Browne. Colour was good, breathing quiet and regular; air-way satisfactory; pupils fully dilated, and just reacted to light. A broad ligament cyst and a pelvic abscess containing offensive pus were found. At this stage, forty minutes after the beginning of induction, fits began, apparently initiated by the addition of a further two or three drachms of ether to the mask. Respiratory rhythm was interrupted, and in a few moments clonic movements of the jaw, head, and neck began, which rapidly spread to the whole body and limbs. The spine was slightly arched, and the abdomen and chest partly lifted from the table, the legs were beating on the foot of the table, and the arms jerking spasmodically. The patient was not in the Trendelenburg position. Respiration had ceased, though a few jerky shallow breaths were taken at intervals. After a minute or two the blood from the site of operation was deeply cyanosed, though the colour of the face was only slightly so. The operation was suspended, the mask removed, and a full stream of oxygen given. Convulsions lasted for about four minutes, and then ceased for one minute. They recommenced, and continued for a further three minutes approximately. When they finally ceased the colour improved and 1/4 grain of morphine was given. The rest of the operation was completed as rapidly as possible without further anaesthetic. The fits did not recur.

The patient recovered consciousness in the ward in the normal time, and has suffered no further ill effects. The anaesthetic had been administered for forty minutes, from the time of beginning the induction to the time of onset of fits. Open ether was the method, 12 ounces being used in all. The ether (aether puriss. B.D.H.) on analysis contained no trace of peroxide or other impurity. The patient operated on before the case in question had had the same ether with no ill effects. The case under consideration, moreover, had been operated on nine months previously, open ether being used on that occasion without untoward effect. She had received on each occasion 1/75 grain of atropine before the operation.

This case illustrates Dr. Blomfield's point, stressed in his letter in the *Journal* of June 20th, that these fits occur during deep narcosis only. Clonus during induction with ether is relatively common and harmless. The points to be stressed in this case are: (1) the patient was deeply anaesthetized when fits began, with a wide pupil barely reacting to light; (2) the air-way was satisfactory and the breathing normal up to the moment of onset of convulsions, and the colour was good; (3) cyanosis did not appear until the fits had been in progress for a minute or two.

Sykes (*British Medical Journal*, June 21st, 1930) states: "True ether convulsions are *not ushered in by cyanosis*," and his own patient died before it was pronounced. The fits in my own case were clearly not asphyxial in origin, nor did they resemble the typical jactitations of asphyxia. It seems probable that some cases of convulsions during deep anaesthesia *have* been due to asphyxia, and have been confused with those where asphyxia was not present. This may account for the variation in mortality figures quoted, which vary from 25 to 100 per cent., since fits of purely asphyxial origin have by no means necessarily a fatal termination. My own case illustrates the fact that true "ether convulsions" are also not necessarily fatal.

The theories so far advanced as to their causation are so varied and contradictory that the real cause is evidently unknown. Sykes sums up most of these theories in his article referred to above: simple over-dosage; atropine poisoning; over-oxygenation; under-oxygenation; instability of the nervous system, notably in children under

10 ; toxaemia ; impurities in the ether ; superheating of the ether—all these, severally or in combination, with one or more other factors, have been blamed. In the case above recorded, however, toxaemia was present, and this is the factor which appears most universally to take part of the blame in the recorded cases.—I am, etc.,

W. M. Priest, M.R.C.S., L.R.C.P.

University College Hospital, July 25th.

APPENDICO-CAECAL INTUSSUSCEPTION

Sir,—Dr. E. N. MacDermott, in recording a case of appendico-caecal intussusception in the *British Medical Journal* of May 9th, states that it is not mentioned in the usual textbooks or in Clubbe's monograph, and suggests that it may not be so rare a condition as it is usually considered. It is mentioned in the second edition of my book, *The Diagnosis and Treatment of Intussusception*. As to its frequency, it may be interesting to note that during the last thirty years 1,055 children have been admitted for intussusception at the Royal Alexandra Hospital for Children, Sydney ; and of that number intussusception of the appendix was found twice.—I am, etc.,

Charles P. B. Clubbe.

Rose Bay, New South Wales,
June 23rd

INFARCTION OF THE HEART WITH PERICARDIAL EFFUSION IN A PHTHISICAL SUBJECT

Sir,—The interesting case described by Dr. Morland in your issue of May 30th differed from that reported by Dr. Yusuf and myself (May 9th, p. 794) in that the chief focus of disease in the former seemed to be in the neighbourhood of the pericardium, while in the latter there was extensive infiltration of the upper parts of both lungs, without evidence of mediastinal involvement. The hilar shadows were not dense, and there were no pressure symptoms The parts of the lungs adjacent to the pericardium were undoubtedly diseased, but we do not think that there could have been an irruption of tuberculous material into the pericardial sac. No increase in the cardiac dullness was detected until about three weeks after the initial attack of pain, although daily examinations were made. A pericardial friction rub was heard about ten days previously.

The result of paracentesis indicated tuberculous infection of the pericardium. In view of the severity of the original disease, we are inclined to think that this was of haematogenous origin.—I am, etc.,

T. A. Hughes.

Kashmir, India, July 6th

REFRESHER COURSES FOR SHIP SURGEONS

Sir,—The letters from Dr. Haslett Frazer and Dr. H. W. Webber indicate that the question of post-graduate instruction has exercised the mind of the ship surgeon. The conditions of service, as pointed out by Dr. Haslett Frazer, have steadily improved, and *pari passu* an increasing demand for special courses has made itself evident.

It was with a view to implementing that demand—with a view not only of maintaining but of raising the standard of professional efficiency on shipboard—that a committee was formed last year. This committee, convened by the British Medical Association, undertook to consider the question of post-graduate instruction for ship surgeons in all its aspects. As a result of their deliberations it was decided to institute *ad hoc* courses, as opposed to the too diffuse instruction afforded by ordinary post-graduate teaching in special or general subjects. These courses were divided into three separate parts, so that individual needs could be more easily satisfied. They comprise: (1) ship hygiene ; (2) tropical medicine and hygiene ; and (3) a refresher course in general clinical subjects. Each part is self-contained, and can be attended separately, so that the individual surgeon can take all three parts in succession, or select that part which is more particularly suited to himself and the conditions of his work.

The task of providing the necessary instruction has been undertaken by the Seamen's Hospital Society, generously assisted by the School of Tropical Medicine and Hygiene. The courses have been planned with a view to the elimination of the unnecessary and the presentation of the necessary in a practical form. Experience will show to what extent the scheme of work must be modified to adapt instruction to the requirements of the service. The long and close association of the Seamen's Hospital Society with the mercantile marine, and the determination of the professional staff, are sufficient guarantee that no effort will be spared to make this venture a success.—I am, etc.,

Percival P. Cole,
Dean, London School of Clinical Medicine.

London, W.1, July 23rd.

THE NEW ZEALAND EARTHQUAKE

Sir,—As an eyewitness, and as one of the medical men who worked throughout the period of the earthquake disaster in Napier, New Zealand, may I correct the impression conveyed by Dr. Biggs in the article which appeared in the *Journal* of May 16th—that an organized medical service was formed immediately the calamity occurred.

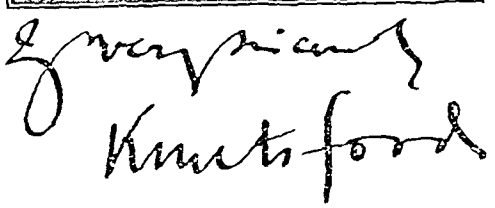
During the first forty-eight hours following the earthquake there was no organization of medical services, each practitioner working almost as a unit, expecting that someone would rise to the occasion and co-ordinate their individual efforts. At the end of this time the emergency surgical work had been completed, and Dr. Allan Berry, who had done the major part of this work at the temporary hospital on the racecourse, asked that the earthquake victims should be evacuated immediately. In his capacity as medical superintendent Dr. Biggs ignored this request and friction arose. On the following day the public health authorities from Wellington took control of the hospital, and the evacuation of these patients was expedited. It can be realized that by this time the whole country had sent its reserves of doctors and nurses into the stricken area, but many of them, after offering their services at one unit or another, finally applied at the racecourse hospital and were being sent home again, as all emergency work had been done.

It is incorrect to state that even as late as Thursday, the third day after the disaster, all medical practitioners were invited to co-operate in what work still remained to be done ; as the practitioners of Napier are listed as loyally responding to this call, it suggests that Dr. Allan Berry and Dr. Harold Berry failed in some way to do their duty in the emergency. Dr. Allan Berry did a great deal of surgical work at the racecourse hospital, and very good work throughout the entire period afterwards. It is out of place here to itemize his work or praise him above the other men, as each gave to the extent of his capacity.

The emergency medical services at Napier were evolved by individual effort, and have only been co-ordinated and organized in Dr. Biggs's article.—I am, etc.,

C. Skinner.

Enfield, July 31st.



Obituary

VISCOUNT KNUTSFORD

Chairman of the London Hospital

In our last issue we briefly recorded the death of Sydney Holland, second Viscount Knutsford, after an abdominal operation, at the age of 76. His untimely death—untimely because he was apparently capable of many years of vigorous and useful work, and because his long-lived ancestry entitled us to hope for his survival for at least another decade—demands further notice, for though he was not allowed to follow his youthful inclination and become a member of our profession, his activities were for the last thirty-five years closely bound up with medical affairs.

He was born in 1855, the elder of the twin sons of Henry Holland, first Viscount, who was at one time Secretary of State for the Colonies in Lord Salisbury's administration. Through his mother, Elizabeth Hibbert, he was great-grandson of Sydney Smith, Canon of St. Paul's, well known for his wit and wisdom. He had a direct connexion with the medical profession through his paternal grandfather, Sir Henry Holland, physician to the unlucky Queen Caroline, and later physician in ordinary to Queen Victoria, probably the most fashionable, and to the lay public certainly the best-known, physician of his time

Sydney Holland was educated at Wellington, of which, and of its then head master Benson, he does not give a very favourable account in his autobiography. At Trinity Hall, Cambridge, he enjoyed himself, and gained distinction as a swimmer and as captain of the college boat club. He left Cambridge with the degree of LL.B., and was called to the Bar by the Inner Temple in 1879. First at the Common Law and then at the Parliamentary Bar, he had a fair measure of success, but a carriage accident in 1888 resulted in a probable fracture of the base of the skull, followed by increasing deafness, and at the same time loss of smell and taste from damage to the olfactory nerves. This disability led to his abandoning the Bar as a profession and turning his attention to business. His maternal grandfather, George Hibbert, had been the first chairman of the board of directors of the East and West India Dock Company, and he still possessed an interest in the company, of which he was destined to be the last chairman. In 1888 the affairs of the company were in a bad way until after Mr. Holland became a director, when the position improved so much that in 1908 the company was taken over by the Port of London authority on terms satisfactory to the shareholders. In these negotiations Sydney Holland came into contact with Mr. Lloyd George, who formed a favourable opinion of him as a man of business. As chairman of the Dock Company Holland had to fight a long and bitter dock strike. Holland was never the man to do anything by halves. Having assumed the responsibility of chairman of the Dock Company he felt responsible for the well-being of its employees, and when one of them became an in-patient of the Poplar Hospital for Accidents he promptly paid him a visit. The man complained bitterly of his treatment by the matron and other lay officials, and Holland found the complaints amply justified; and when, soon afterwards, he was asked to take the chair at the annual meeting in June, 1891, he did so. What happened then is best described in his own words:[1]

"I drifted into hospital work. . . . It was reported that a large number of working men—governors by virtue of their subscriptions—were going to attend the meeting with a view to turning out the committee as a protest against the treatment their fellows had received there. I took the chair, and thought the working men made out an extremely good case, and that the reply made by the committee was most unsatisfactory. I told the meeting what I thought, rather to the indignation of the committee, and then the leader of the working men who had acted as spokesman did a very nice thing. He said they had no wish to hurt the hospital, and, if I would adjourn the meeting for a fortnight and inquire into the matter, they were perfectly content to leave it where it was. This I did, and in the course of that fortnight I found that things were a great deal worse than even any of them had any idea of. The hospital was in a filthy state. . . The drains were wrong. The ventilation was bad. . . . The nurses were a very inferior class of women, and the matron, who had been very efficient when appointed, had become unfit to hold her position. The committee did not support me, and ended by saying that if I thought I could put things right I had better do so. Nothing else was open to me except to try, so I accepted the challenge."

Needless to say, he succeeded. The hospital at that time had thirty-six beds, and had £8,000 put away towards rebuilding, which was badly needed. Holland started to beg, and in a few years the hospital was rebuilt at a cost of £70,000, the reserve of £8,000 had grown to £54,000, and the hospital was made one of 103 beds with its isolation block, and has never once been in debt. This achievement was but a harbinger of others that were to come after he became chairman of the committee of the London Hospital in 1896. When he was offered this chair he stipulated that he should have charge and control of all appeals for funds, and for the rest of his life, as the Hon. Sydney Holland or Viscount Knutsford (his father died in 1914), he never ceased to collect money for his beloved "London," within the walls of which he breathed his last. Stories of his ready wit, and of the soft answer which turneth away wrath, are plentiful. The real man beneath the jester was a great, warm-hearted philanthropist, who dearly loved his fellows.

[1] *In Black and White.* By Sydney Holland, Viscount Knutsford. London: Edward Arnold. 1926. (P. 134.) (See review, *British Medical Journal*, 1926, ii, 845.)

In 1916 he was knocked down by a motor lorry, and lay unconscious for a week. The injury thus inflicted still further increased his deafness, but did not lessen his mental and physical activity. In 1921 Lord Knutsford's private secretary, Mr. Neville Langton, wrote an entertaining and sympathetic book about his chief, which he called *The Prince of Beggars*, a title which the *Times* adopted for its obituary notice. Sydney Holland was all that, but he was a great deal more. He not only raised huge sums by methods which largely depended for their success upon his personality, but he had the foresight to see the ideals for which those sums were wanted, and to plan and organize a great modern hospital, with its medical school, on a scale and with a thoroughness hitherto unthought of. He was a great organizer, whether he was planning an appeal for funds, the reform of nursing arrangements, or the installation of new and up-to-date operating theatres.

The services of Lord Knutsford to the cause of medical research were notable. He was always ready with pen or person to defend it against antivivisectionists, and his last contribution to our columns, on September 20th, 1930, was an appeal for subscriptions to the funds of the Research Defence Society, of which he had been chairman for many years. In his covering note to the Editor he said: "Can you find space for this? . . . We are fighting for your Profession and against very rich Societies and people."

[The photograph reproduced is by G. C. Beresford, London.]

BOUVERIE McDONALD, M.D.

Formerly M.P. for Wallasey

Dr. Bouverie Francis Primrose McDonald died last month after a long illness. He was born in Edinburgh on April 13th, 1861, and was educated at the Edinburgh Academy and University, where he graduated M.B., C.M. in 1884, and in 1886 took the degree of M.D., the subject of his thesis being "Virulent outbreak of rotheln in Brampton." Dr. McDonald began the practice of medicine in Penrith, and then moved to Cheshire, residing first at Liscard, and afterwards at New Brighton. There he rapidly established an extensive practice, and gained the esteem and devotion of a large clientele. He did not confine himself to his professional duties, but took part in many projects which were at that time engaging the attention of the residents, for he was keenly interested in all the various developments then taking place, as the increase, both in population and building, was phenomenal. He remained in Wallasey for forty-five years, and during that time held many appointments, including those of surgeon to the Seacombe Cottage Hospital and the Victoria Central Hospital, consulting physician to the Wallasey Dispensary, medical officer and public vaccinator to the Birkenhead Board of Guardians for North Wallasey, and member of the Cheshire County Council. During the war he was assistant county director, British Red Cross Society.

A colleague writes:

Dr. McDonald was a clever and fearless yet conscientious surgeon, and a man with tremendous confidence in himself and his own opinion. He had a most pleasing manner, and a charming, captivating smile, and was both trusted and beloved by his patients. Some idea may be gained of Dr. McDonald's strenuous work during the years he was in practice in Wallasey when it is mentioned that was attended at the birth of 2,200 infants and vaccinated British 0 babies. In an outbreak of small-pox in 1901 he uestion ted 4,000 persons in six weeks. He was a very ll its aspects during the war, and if he did not "do his bit" ecided to institu certainly did it at home. He presented e to the borough on the outbreak of e was a very pronounced and active Conservative. In 1917 he was asked to stand as candidate for the new Wallasey Division, and in the General Election of 1918 he was returned as its first Member of Parliament, with a majority of over 10,000 votes. He remained a member till 1922, and during these years he served on several committees. On his retirement he was presented with his picture in oils, and this portrait now hangs on the walls of the Town Hall. He was for many years a justice of the peace for Cheshire and Wallasey.

Another colleague writes:

Dr. Bouverie McDonald came to Wallasey in 1886, where he soon built up for himself a large and successful practice. At an early date he was appointed honorary surgeon to the Wallasey Dispensary, and also to the Seacombe Cottage Hospital, which in 1901 became the Liscard Central Hospital. In these two hospitals he performed many operations, as well as treating many medical cases. Later on, he threw himself into political work in the Conservative interest, became president of the local Primrose League, and then president of the Conservative Association. After his election to the House of Commons, parliamentary duties took him to London for a good part of the year, and as his time and interests were so fully occupied he resigned his post as surgeon to the Central Hospital before the expiry of his time limit. As that Parliament drew to an end, he announced that he did not intend to stand again, and thenceforward devoted himself to his practice. A few years ago he gave up work in Wallasey, and retired to Croydon, where he died. In his earlier years he was a distinguished athlete in Rugby football and in cricket, and was a good tennis and billiards player. He gloried in his Highland ancestry, and at some of his hospitable entertainments at his residence, Ivor Lodge, delighted in turning out in full Highland costume and tartan.

Miss HILDA MARGARET BYLES, M.B., B.S., of the Margaret Memorial Hospital, Hankow, died from pneumonia on July 25th. A member of the well-known Yorkshire family, she was born at Headingley, Leeds, on August 28th, 1879. While a student at the London School of Medicine for Women she was a church member of Whitefield's Central Mission, Tottenham Court Road. She left England in June, 1907, to take charge of the hospital at Hankow which had been founded as a memorial to Mrs. Margaret Griffith-John, widow of the missionary pioneer whose centenary is being celebrated this year. Dr. Byles was a little woman of amazing energy and capabilities. She was a close friend of the Chinese, and sympathized with them in their nationalist aspirations. She did a fine missionary work among them, both by the force of her own example and by her medical work, especially through the training in the women's hospital of Chinese nurses for obstetric work in the homes of the people.

The Services

Surgeon Rear-Admiral E. A. Penfold, D.S.O., has been awarded the Greenwich Hospital pension of £100 a year, from June 3rd, in the vacancy created by the death of Inspector-General H. C. Woods.

DEATHS IN THE SERVICES

Lieut.-Colonel William O'Byrne White, R.A.M.C. (ret.), died on March 21st at Tralee, aged 87. He was born at Carlow on September 27th, 1843, was educated in Dublin, and took the L.R.C.S.I. and L.R.C.P.Ed. in 1864. Entering the Army as assistant surgeon on March 31st, 1865, he became surgeon major after twelve years' service, and retired, with an honorary step of rank as brigade surgeon, on April 25th, 1885. After retirement he was employed at Tralee from April 25th to September 26th, 1908, and was also re-employed during the war of 1914–18. In the old regimental days he served in the 1st Foot, the Royal Scots.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

Parliament adjourned for the Long Recess on July 31st Both Houses are due to reassemble on October 20th The report and third reading of the Town and Country Planning Bill are down for October 22nd and 23rd Provision is made that the Speaker, after consultation with the Government, may call the House together before October 20th if public interest requires.

On July 31st the Royal Assent was given to the Finance Act, Probation of Offenders (Scotland) Act, Marriage (Registration) Act, Adoption of Children (Scotland) Act, Housing (Rural Authorities) Act, Bethlem Hospital (Amendment) Act, and to other Acts

Dr. Salter and Mr. Somerville Hastings are leaving for Russia at the end of this week, and during their tour will investigate public health organization in that country

On July 28th, at the House of Commons, the work of medical men in Parliament was discussed at a dinner *party given by Dr Fremantle, and attended, among* others, by Mr Neville Chamberlain, Sir Walter Fletcher, Dr. Salter, Mr Somerville Hastings, Dr Alfred Cox, Dr A. F. Hurst, and Sir G. Lenthal Cheatle

The Education Estimates

Mr LEES-SMITH presented the Board of Education Estimates for England and Wales on July 16th. He said that, on going to the Board, he found a gap in the educational system between the years of 1 and 5 Most mothers ceased to attend the maternity centre at the end of the first twelve months of the child's life, with the consequence that, when the children came to the infant school at the age of 5, 20 per cent suffered from physical defects which, in hundreds of cases, impaired their vitality and poisoned the rest of their lives One method of dealing with this evil was the establishment of nursery schools, but the total number of places in such schools, built, in course of erection, or proposed for the next two years, was only 3,300 He awaited the report of the Consultative Committee of the Board of Education, which was going closely into the proposal for nursery schools and alternative proposals for nursery classes in infant schools Nursery schools were part of the medical work of the Board The backbone of that medical work was the medical inspection of the normal child thrice during the school career He took as the test of a local authority the provision made for following up this medical inspection by nurses, medical officers, clinics, specialists, hospital treatment, special schools, and orthopaedic schemes Steady and continuous progress had been made in all those *for some years, and had continued quite* rapidly even during the financial stringency of the last twelve months Dental treatment, however, was not one of the most successful parts of the work The new type of open air school building, with glass sides which opened, had a wonderful effect on the health of the children Last year £9,000,000—the largest sum ever spent in a year—had been approved by the Board of Education for new school buildings The number of classes with over fifty pupils in each had been reduced from 11,000 to 9,000 Mr Lees Smith referred to the success of the former elementary school pupils who had gone to universities with State scholarships Of the men, 52 per cent gained first class honours, of the women 28 per cent In conclusion, he said he was constrained by financial difficulties and the realization of many hopes might have to be postponed

Mr PERCY HARRIS said that much expenditure was made necessary because of neglect of the child before it came into the care of the educational service If the work of the Board of Education was co ordinated with that of the Ministry of Health, instead of being divorced as at present, much of the expenditure on the school medical service would be saved Only a quarter of the children who required it received dental treatment. In some areas there was no official organization for the purpose He commended the complete system for dental treatment of school children which had been instituted in New Zealand At least a third of the school buildings in the country should be altered to admit sunlight and air freely.

Mr BEAUMONT asked Mr Lees Smith to impress on local authorities the need for increasing the number of places in special schools and special institutions for mentally deficient children to take these out of the ordinary elementary schools.

Mrs MANNING said that the mentally deficient child had been completely neglected She recalled the answer Mr Lees-Smith gave recently showing the small number of schools built for such children since 1926 The Minister had said that *in 1930 the Board did not refuse* any local authority leave to construct a special school for mental defectives, but only one application was received that year The Estimates before the House showed an increase of £475 000 in the vote for special services, but £375,000 of that would be spent on school medical services and special schools and £100 000 on the provision of meals, *leaving nothing for the mentally* defective child Did members know that there were 340 000 mental defectives in the country, that from 1906 to 1929 mental deficiency doubled, and that the incidence per 1 000 school children was 20 7 in urban and 39 7 in rural areas? The Wood report asserted that 61 per cent of subcultural *mental defectives came from homes below the average in* wealth and 25 per cent from the poorest slum homes Mental deficiency was a social and not a pathological problem She had taught mentally defective children, and knew that by careful, patient methods they could be given a place in society Mr Lees Smith had said that legislation was required She warned him that if it was on the lines of the Wood report every teacher would oppose it

Lord EUSTACE PERCY recalled that in an annual report Sir George Newman had expressed the view that nursery schools were really a blind alley, and that there must be a wider policy combining the nursery school idea with the health centre idea.

Mr SOMERVILLE HASTINGS said that the school medical service dealt too much with treatment and too little with the prevention of diseases The school medical officer was like the grocer who sorted over the oranges and put the bad ones aside Six minutes, the average time spent by a school medical officer in inspecting each pupil, was very short Last year eight local educational authorities made no provision for the dental treatment of their scholars The report of the Board showed that less than one third of those in need of dental treatment received it In the years of medical inspection dental inspection was generally omitted The Board should see that the charge for the medical and dental treat*ment of scholars was not made a deterrent* He regretted that in some places a higher charge was made for stopping teeth than for their extraction When the school medical officers were appointed they were asked to provide an annual review of the hygienic conditions of the schools and of the way hygiene was taught, but in the report for 1929 of the Medical Officer of the Board of Education for the London County Council the only thing he could find about hygiene of the schools was plans and details of four new open air schools There should be more teaching of hygiene in schools What became of the medical records which were kept of the children attending some schools? Some local education authorities had applied to the Board of Education for permission to transfer the medical records of children when they left school at the age of 14, so they could be passed to the panel doctors when the children reached 16 The Board had refused That was short-sighted, and he asked for the decision to be reconsidered

Mr MORGAN JONES, replying for the Board, said that in two years actual, approved, and prospective nursery schools had been raised from twenty eight to one hundred He agreed that the provision for mentally deficient children was inadequate To provide special accommodation in rural areas was a difficult matter, yet there was more mental defect among the rural population A residential special school cost about £90 per place Parents were indisposed to let such children go to residential schools, and the law as it stood gave no power to compel them He admitted there were profound differences of opinion on the wisdom of accepting the general conclusions of the Wood Committee

A discussion followed on education in Scotland

National Insurance Medical Service

Mr GREENWOOD said in reply to Commander Kenworthy on July 30th that he was unaware of any regulations whereby insurance doctors were forbidden to give certain medical treatments to panel patients which would be given to private paying patients and which treatments were in general use in private medical practice. Insurance practitioners were required in all ordinary cases to give to their patients all proper and necessary medical services other than those involving the application of such special skill and experience as was not to be expected of general practitioners as a class, and to order or supply such drugs and prescribed appliances as were requisite for the treatment of any patient.

In reply to Mr Graham-White, on July 30th, Mr GREENWOOD said the approximate amount of national health benefit paid in any recent year in respect of sickness arising from rheumatic diseases could only be obtained after special investigation. It had, however, been estimated on good authority that one-seventh of the total invalidity among insured persons was due to rheumatic diseases. On this basis the cost involved for the year 1930 would be about £2,500,000.

Replying, on July 30th, to Mr T. Lewis, Mr GREENWOOD stated he had already addressed to all insurance medical practitioners a memorandum concerning the issue of medical certificates to insured persons. Provision had also been made by an amendment of the Medical Benefit Regulations for dealing with cases where medical practitioners were found, after due inquiry, to have failed to exercise reasonable care in the issue of certificates.

On July 30th Mr GREENWOOD stated that the total of the surplus funds of approved societies and branches as ascertained at the second valuation amounted to £42,413,319, from which amounts totalling £26,619,161 were certified for distribution in additional benefits in the ensuing quinquennium. The summarized results of the third valuations would be issued shortly after the recess.

Mr GREENWOOD told Commander Kenworthy, on July 30th, that no regulations under the National Health Insurance Act precluded an insurance doctor from administering injections of asthmalysin for the cure of asthma, nor was he aware of any case in which a surcharge had been made for giving such treatment. Asked whether a doctor who prescribed this drug could be called upon to justify its prescription and be surcharged if he were not able to make out his case, Mr Greenwood said the regulations against extravagant prescribing might operate in certain cases.

Diagnosis of Cancer

Mr GREENWOOD told Dr Morris Jones, on July 30th, that his attention had been drawn to the recent investigations of Dr Bendien into the possibility, by means of blood tests of making certain diagnosis of cancer in its early stages. In common with all other investigations into this disease, this would be considered by the Departmental Committee on Cancer on which the Medical Research Council was represented.

Asked by Sir N. GRATTAN DOYLE whether any special financial assistance was being given by his Department to further this line of research under hospital conditions in Great Britain, Mr GREENWOOD said that any recommendations of the Departmental Committee on Cancer about further investigation would receive his consideration.

Ventilation of House of Commons.—In reply to Mr Strauss, on July 29th, Mr LANSBURY stated that in view of the representations which had been made to him by members of all parties, and particularly by the medical members of the House, he proposed to call for a joint report from the Government chemist and the Department of Scientific and Industrial Research on the air and general ventilation conditions throughout the whole of the House of Commons.

Centres for Actinotherapy.—On July 28th Miss LAWRENCE told Mr Mills that, since April 1st, 1930, the approval of the Ministry of Health had not been necessary to the provision of centres for artificial sun ray treatment, except where the centre was to be used for the treatment of tuberculosis, and was to be provided in premises not previously approved for that purpose. Up to April 1st last 269 centres had been approved. In the last two financial years there had been seventeen applications from local authorities.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

At a congregation held on July 28th the following medical degrees were conferred:

M.D.—*R. W. B. Lillis, *J. E. D. Crozier, A. E. Nash, W. D. Newcomb, A. W. Spence, L. E. Llewellyn.

M.B., B.Chir.—*R. H. B. Snow.

B.Chir.—*J. H. W. Lyle, R. G. Orr, C. R. T. Lane, H. S. Bucklund, P. G. Scott, H. C. Stewart, J. W. Summerhays, W. A. Teel.

*By proxy.

UNIVERSITY OF LONDON

The following candidates have been approved at the examination indicated:

M.S.—*Branch I (Surgery)*: M. Coleman, R. S. Pilcher. *Branch IV (Laryngology, Otology, and Rhinology)*: A. G. Tresidder.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

The following candidates have been approved at the examination indicated:

ACADEMIC DIPLOMA IN BACTERIOLOGY.—Dora C. Cockrock, Catherine B. Hendry, C. O. Karumakaran, A. R. Martin, A. I. Oxford (awarded mark of distinction), J. W. Priestley, W. D. B. Read, G. Robinson, Pauline C. Witherow.

GUY'S HOSPITAL MEDICAL SCHOOL

The following awards of senior science scholarships have been made:

War Memorial Scholarship (£100): M. Spink. Open Senior Science Scholarship (£80): J. R. Dickinson.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

An ordinary meeting of the Council was held on July 30th when Mr R. P. Rowlands, Vice President, was in the chair.

Diplomas

Diplomas of Membership were granted to the following candidates:

A. M. M. Ah, F. Anthony, Grace M. Archer, H. G. F. Arthure, Doris Ascough, P. J. Ashby, E. S. Asiedu-Ofei, E. J. Baldwin, A. A. Baliga, K. Baxter, R. A. Beaver, W. D. Bell, W. H. Bradbeer, R. J. B. Broad, G. O. Brooks, J. M. I. Burtenshaw, C. R. Caffry, Beatrice L. Campion, A. M. Cantor, P. Chandra, E. I. Claridge, Barbara G. C. Clarke, R. C. Cohen, C. P. Collins, J. G. Connell, H. A. Constable, A. B. Cook, I. J. Current, D. Davidson, A. S. H. Davies, J. R. Duffield, S. Durham, K. A. Earle, G. G. M. Edelsten, G. R. Ellis, F. St. J. C. Emerson, L. S. Everett, P. B. Fernando, G. A. Fleet, M. J. Garber, H. A. Garrus, V. Glass, S. Goode, C. E. D. H. Goodhart, G. H. Good, W. H. Greany, H. I. Green, A. Greenberg, H. J. Griffiths, Hilary S. M. Hadaway, Winifred S. Hall, H. A. R. Hamilton, D. C. Harris, A. E. I. Hart, E. S. Harverson, J. R. Heming, I. Hinden, L. C. Holland, J. H. Hughes, Bhagwagna Inmitch, A. M. James, J. L. Jenkyn Thomas, W. P. Jenson, D. Johnson, Annie L. Jones, Esther P. W. Jones, Alice M. Kaye, C. A. Keane, Mary J. R. Kennard, S. J. Knight, M. Kosloff, N. L. Lamb, J. S. Lane, P. R. K. Lane, A. M. P. Laurent, H. G. Letcher, I. M. A. Lewis, H. L. Light-stone, M. A. Lloyd, J. W. McLaren, J. W. Macmillan, G. A. M. Madel, J. W. Meanley, L. K. K. Menon, A. K. Monro, P. B. Moroney, W. J. Morris, I. Moshinsky, H. C. Muirhead, R. W. C. Murray, T. I. B. Noble, L. G. Norman, Catherine O'Connor, Angela M. S. Ofenheim, Lily M. O'Hanlon, G. I. Petty, A. J. Potter, Hamed M. Pulston Jones, I. Rabinovitch, G. I. Rees-Jones, D. A. Richardson, J. C. Roberts, H. D. Robertson, C. H. Rogerson, N. L. Rusby, P. C. Sanyal, M. N. Sardana, I. Schnire, I. Sharp, F. W. H. Shawcross, M. H. Sherwell, Rosalie Shoenberg, A. B. Simmons, H. Simmons, H. Singh, J. C. Smith, D. G. Snell, R. G. W. Southern, Gladys M. G. Spencer, Violet Spiller, A. A. Sreenivasan, T. Standring, C. Starkie, V. Swaminathan, R. A. Sykes, A. K. Talkhan, G. Tattersall, Winifred P. Thomas, W. I. Townsend-Coles, J. G. Vincent-Smith, A. B. Waters, J. H. Way, G. Wells, M. Westwood, S. O. Widmann, E. W. M. Williams, Dorothy Woodman, S. L. Wright, A. H. Zaar, J. Zeitlin.

Diplomas in Tropical Medicine and Hygiene were granted jointly with the Royal College of Physicians, to the following:

E. S. Adderley, B. P. Baliga, C. J. H. Brink, W. A. Burnett, R. Caldera, H. Chaudhuri, H. D. Cronyn, B. R. Das, C. H. Howat, A. J. Johnson, J. B. Khambatta, R. K. Khanna, P. B. Lee-Potter, H. W. H. McClelland, S. H. Moore, Ethel Morris, J. L. Rankin, J. A. Rosset, A. Sivalingham, M. M. Syddiq, J. Taylor, P. G. G. Unnithan, L. A. J. Wiles, A. W. Williams, W. J. S. Winn.

Diplomas in Ophthalmic Medicine and Surgery were granted jointly with the Royal College of Physicians, to the following:

M. Basheer, G. H. B. Black, M. G. J. Booysen, G. A. Brew, Eleanor M. P. Brock, C. Budden, A. Campbell, M. Franks, A. W. Green, Lieut.-Col. F. G. Kennedy, I.M.S., Edith G. Limrey, S. Macky, K. C. S. Menon, Catherine J. Orr-Ewing, B. W. Roffey, K. Saha, R. Sampson, M. N. Sardina, R. C. Tarapore, H. L. St. V. Welch.

Primary Fellowship Examination in Toronto

On the nomination of the Canadian Medical Association, Dr. J. C. B. Grant, Professor of Anatomy, and Dr. C. H. Best, Professor of Physiology, were appointed assessors for the Primary Examination for the Fellowship to be held in Toronto next October.

CONJOINT BOARD IN SCOTLAND

The following candidates have been approved at the examination indicated:

FINAL PROFESSIONAL EXAMINATION.—G. Ameratunga, S. Pativagoda, T. F. Kirkpatrick, H. J. Smith, H. T. Anthoniez, T. A. M. Ashforth, G. L. Whitton, C. F. W. de Saram, B. A. Armitage, M. W. Joseph, L. J. Goggins, R. J. F. L. Talbot, C. M. Douglas, G. W. Puvimanasinghem, S. R. Iyengar, S. Grasse, F. A. Ebert, A. M. C. Stephenson, I. M. Sclare, J. A. Walsh, W. Kelly, M. Smellie, S. V. Rajah, M. E. Rubin, A. G. Williams, G. D. Morgan, P. A. V. Pillai, H. F. Ezzat, S. Freeman.

SOCIETY OF APOTHECARIES OF LONDON

The following candidates have passed in the subjects indicated:

SURGERY.—K. W. Bruce, G. B. Carter, M. Ditton, A. A. Grace, B. N. Halder, R. Schauder, C. F. Williamson.

MEDICINE.—H. W. Davies, G. R. Germany, A. R. Madden, O. L. Matthews, M. R. Tuteur-Samuel.

FORENSIC MEDICINE.—O. A. P. Clark, R. R. Clipstein, G. Handelsman, O. L. Matthews, C. Morgan, M. S. Mules, Grantley Smith.

MIDWIFERY.—G. B. Carter, Sidney Smith, V. M. White.

The Diploma of the Society has been granted to Messrs. G. R. Germany, A. R. Madden, O. L. Matthews, R. Schauder, M. R. Tuteur-Samuel, and C. F. Williamson.

Medical News

The Fellowship of Medicine has arranged two special courses for August—namely, a course in urology now in progress at the All Saints' Hospital until August 29th, and a course at the Queen's Hospital for Children from August 17th to 29th. Lunch and tea are kindly provided by the hospital authorities. Fee, £2 2s. A comprehensive course will be given at the Brompton Hospital from September 7th to 12th (fee £3 3s.); an afternoon course at the Infants Hospital from September 14th to 26th (fee £3 3s.); psychological medicine at the Bethlem Royal Hospital from September 8th to October 3rd; ophthalmology at the Central London Ophthalmic Hospital from September 15th to October 10th (fee £3 3s.). A revision course will be given at the Westminster Hospital from September 14th to 26th (fee £5 5s.), and a similar course at the Metropolitan Hospital from September 28th to October 10th (fee £3 3s.). Detailed copies of syllabus may be obtained from the Fellowship of Medicine, 1, Wimpole Street, W.1.

The autumn list of medical post-graduate courses in Berlin has now been issued. This booklet (printed in German) gives full details of the various special classes arranged for the next few months, and also an account of the permanent educational facilities which are available. Among the courses are internal medicine, from October 5th to 17th; children's diseases, during the same period; urology, from October 15th to 21st; and medical psychology and psychotherapy, from October 26th to 31st. Further information and copies of the booklet may be obtained from the Medical Information Bureau, Kaiserin Friedrich-Haus, Luisenplatz 2–4, Berlin, N.W.6.

Mr. Walter Bell, F.S.A., will conduct parties over the Tower of London on August 12th and 26th, at 2.30 p.m., in aid of King Edward's Hospital Fund for London. Mr. Bell will give short addresses on the Tower, its history and associations, before making a tour of the building. Application for tickets (price 7s. 6d.) should be made as soon as possible to the secretary of the Fund, 7, Walbrook, E.C.4.

At a meeting of the Paddington Medical Society to be held on Tuesday, August 11th, at the Great Western Royal Hotel, Paddington, at 9 p.m., Dr. A. Baldie will give an address entitled "The alcohol problem."

The first Congress of Medical Geography will be held at Geneva in October, when the subject for discussion will be hepatic cirrhosis.

The Board of Control, with the approval of the Minister of Health, has appointed the following as honorary consultants in connexion with diseases occurring among the mentally defective patients at Rampton State Institution, Retford, Notts: encephalitis lethargica, Professor A. J. Hall, M.D.; diseases of the ear, nose, and throat, Mr. Vincent Townrow; ophthalmic diseases, Dr. E. Gordon Mackie.

An international illumination congress will be held from September 1st to 19th in London, Glasgow, Edinburgh, Sheffield, Buxton, Birmingham, and Cambridge. It has been organized jointly by the National Illumination Committee of Great Britain and the Illuminating Engineering Society, London, and is under the auspices of the International Commission on Illumination.

The fourteenth Italian Congress of Paediatrics will be held at Florence from September 23rd to 26th, when the following subjects will be discussed: (1) empyema in infancy, introduced by Drs. Cocchi of Florence, Laurinsch of Naples, and Nasso and Castronuovo of Messina; (2) encephalitic syndromes in infancy, by Drs. Bergamini of Parma, De Toni of Bologna, and Taccone of Milan; and (3) directions for diet in children's communities, introduced by Drs. Brusa of Milan, Lucca of Turin, and Macciota of Cagliari. Further information can be obtained from the secretary, Professor Bruno Frambusti, R. Clinica Pediatrica, Via Maneli 15, Florence.

Dr. N. F. Seed of Hyde, Cheshire, was successful in his appeal to the Manchester Quarter Sessions on July 30th against a conviction at the Manchester Police Court, when he was fined £20 and had his licence suspended for three years on a charge of dangerous driving; the conviction was quashed.

A new medical periodical, *La Cure Marine*, has been founded, under the editorship of Dr. E. Delcroix, to deal with thalasso-therapeutics and kindred subjects. The editorial secretary is Dr. R. de Haene, 94, Boulevard van Iseghem, Ostend.

The Home Office of the Republic of Mexico has issued an order that no more foreign medical men can be allowed to practise on Mexican territory without authorization.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM* 9861, 9862, 9863, and 9864 (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Autology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediseca Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*, telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*, telephone 24361 Edinburgh).

QUERIES AND ANSWERS

Prepatellar Bursitis

"H. B. G" writes: Can any reader say whether it is safe to empty the fluid from an inflamed prepatellar bursa and inject the quinine and urethane solution used for treating varicose veins? If so, what technique should be followed? Does this bursa ever communicate with the knee-joint?

Lochnera Rosea

Mr J E R McDonagh (London, W) writes, in reply to Dr Dalziel's inquiry (August 1st, p 230) The eclectic school of medicine and herbalists have used vinca, lycopus, and viscum in diabetes for many years An extract of the leaves of one of the evergreen South African Compositae (*Brachylaena dentata*) is a vaunted remedy for the same condition I have injected extracts of these plants into animals, but I have not been able to satisfy myself that they have an action in lowering the percentage of the blood sugar An hydrator effect is exhibited occasionally, but not regularly, and therefore I have not employed them on a large scale in disease I have not found lycopus to be of use in exophthalmic goitre or viscum in hyperpiesia—two conditions allied to diabetes

Effect of Prolonged Injections of Insulin on Subcutaneous Tissue

With reference to Dr Jendwine's letter (June 27th, p 1145) and the inquiry by "M D" (July 4th, p 42), Dr I M Rabinowitch of the Montreal General Hospital sends us reprints of two articles by him on this subject, published in the *Canadian Medical Association Journal* (1928, xviii, 560, and 1929, xxi, 67) The condition (he writes) is uncommon, but not rare, and, at least from experiences so far, it appears to be compatible with good health The cause of it is unknown, but it seems to be a non specific reaction, and is probably the result of repeated trauma Incidentally, an excellent review of this subject will be found in the *British Medical Journal* (1929, i, 597)

Painful Heels

"P" writes, in reply to "Electrotherapist" (July 25th, p 173) I once heard Sir Archibald Garrod (then Regius Professor of Medicine at Oxford) recommend mercury and belladonna ointment for this condition, and I have used a mixture of equal parts of ung hydrarg and ung belladonnae with good results

Income Tax

Request for Balance Sheet

"C A H" took over a practice as from May 1st, 1930 He did not take over existing book debts and it is agreed that he is assessable on the basis of his "bookings" The first year's income and expenditure account has been put in by professional accountants, and the inspector of taxes asks also for a "balance sheet," setting out the assets and liabilities of the practice as at March 31st, 1931—or, alternatively, for a promise to supply balance sheets in future years

*** So far as our experience goes, it is not customary for balance sheets to be asked for or supplied in such circumstances and if the inspector's experience is, as he says, to the contrary we think it must be due to a purely local custom Further, we do not see that balance sheets serve any real purpose in a professional practice, apart from the stock of instruments and drugs and the car, the only assets normally would be the outstanding debts which are ascertained and the total notified to the inspector already The matter is within the jurisdiction of the local or "special" commissioners and we incline to the opinion that if "C A H" maintains his attitude it would be upheld on appeal to either of those bodies With regard to the inspector's request to examine the purchase agreement, the terms with regard to deferred payments are relevant to the settlement of the liability and on the whole we advise "C A H" to send him the original for perusal, or a signed copy for retention

Motor Car Transaction

"B L P" bought a car in 1919 for £650, and in July of this year sold it for £15 and bought a new car of a different make for £243 How should he deal with the matter for income tax purposes?

*** This is an unusually clear illustration of the fact that the taxpayer nearly always loses in the long run if he does not claim annual depreciation All "B L P" can do at present is to claim as a professional expense of the year 1931 the net cost of replacement—that is, £243 – £15 = £228 As tax is chargeable on the amount of the income of the previous year, this means that it will not affect his liability until the financial year 1932-33 As depreciation and cost of replacement cannot be allowed for the same year, he is unable to claim depreciation for 1932-33, but should do so for 1933-34—on (£228 – 15 per cent of £228 =) £194 at 15 per cent

LETTERS, NOTES, ETC.

Operation for Cataract

Personal Experience

"Medico" writes Having had a cataract removed from my left eye during the past nine months I am in entire agreement with Colonel Elliot's statement that the patients themselves are the best judges of the value of operative intervention My cataract was of short duration being first noticed in January, 1929 It was of the ripe soft swelling, soft, cortical type, and the operations were performed in October and November, 1930 During the period of maturation I was considerably handicapped in the early stages by a sensation of "steaminess" of vision on the left side, later replaced by diplopia, worse at night, and eventually the eye became almost completely blind During this last stage I was involved in two accidents, in one of which I had the misfortune to knock down a lady whom I had not seen until after the accident, in the other—a motoring accident—I was run into on my blind side by a slow moving vehicle which I did not observe The extraction of the cataract has naturally resulted in a largely restored left visual field, making walking and driving safe, because even slight movements, although they cannot be focused can certainly be noted with the aphakic eye, and for this reason alone, I consider the operation well worth while The visual acuity has been raised from the counting of fingers held up to light at a distance of 2 inches from the eye, to 6/5 Snellen's types under +11 D correction no cylinder being required, in other words, a really useful professional eye is available should disaster overtake its sound fellow After leaving the nursing home and for some weeks subsequently, diplopia was troublesome but I gradually learned to neglect this effect in much the same way, I think, that the trained non observing eye of the microscopist neglects objects on the bench below While it has to be admitted that one cannot use a corrected aphakic eye in conjunction with its sound fellow, there is much to be seen with an uncorrected aphakic eye and I find it possible, while driving, to close the sound eye and bring my car to a standstill with ease and comparative safety In conclusion, other things being equal, I would strongly advocate the removal of a unilateral cataract in any patient of mine The eye is useless as it is, while a successful operation brings increased comfort and safety of locomotion, and confidence is instilled in the patient should his second eye become affected at a later date

A Substitute for Hand Towels

D Lachlan Grant (Ballachulish, Argyll) writes I was interested in "D P H's" letter on this subject in the *Journal* of June 13th In March, 1929, I advised that the method of drying one's hands by means of hot air be used after washing, the paragraph published being as follows "In many of our public places, restaurants, etc, it would appear to me that another method of drying the hands might be tried instead of the frequently much contaminated roller towel—namely, by means of the hot air blower, such as is now used by hairdressers This method certainly takes a little longer than the usual towel one but a brief series of experiments showed that the time taken was not great, and depended on the temperature and force of the current and proximity of the blower This method of drying is akin to nature's way, and appeared to leave the skin soft and supple" It must be of interest to a number of colleagues to have their attention again drawn to this matter "D P H" quotes the address of the installed machine seen in Paris I have made further inquiries, and find it is in use in several establishments in Scotland—for example, the Public Health Department of Edinburgh University has it installed I understand that the public ones cost from 18 to 21 guineas I myself use at home the ordinary cheaper hair drying type, which gives currents of hot or cold air as desired Authorities, however, seem very slow to appreciate such an idea as hot-air drying, in spite of its obvious advantages

Vacancies

Notifications of offices vacant in universities, medical colleges and of vacant resident and other appointments at hospitals will be found at pages 34, 35, 36 37, 40, and 41 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 38 and 39

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 127

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

97 Cardio-vascular Disease and the Teeth

W LINTZ (*Med Journ and Record*, May 20th, 1931, p 479) discusses the relationship of the teeth to cardio-vascular disease, as indicated by the experimental work of Rosenow and by clinical and post mortem experience Of 349 consecutive patients, the first 125 suffering from cardio vascular disease were studied, with 224 suffering from other diseases, 100 normal persons acted as controls The patients with cardio vascular disease were found to have lost 46 5 per cent of their teeth, as compared with 32 per cent in the case of those suffering from other diseases, and an average of 17 6 per cent in normal people Lintz is satisfied that there is a definite etiological relationship between infected teeth and cardio vascular disease, and that benefit follows removal of the infection and immunization with autogenous vaccines in certain cases The loss of teeth in both health and disease occurs in a definite sequence, the molars being the first and the canines the last to go, 22 per cent more of the upper teeth are lost than of the lower The author considers that the dentist performing the extraction should also conduct the *x* ray examination The loss of teeth was found to be great in essential hypertension and cerebral haemorrhage Good results often follow the eradication of dental infection in angina pectoris, myocarditis, and endocarditis, such infection is a factor also in hypotension.

98 Essential Hypertension

D ADAMAN and J H PRATT (*Arch Int Med*, May, 1931, p 675), from a study of the character and early symptoms associated with essential hypertension (headache, dizziness, weakness, fatigability, irritability, nervousness), consider that they are of psychoneurotic origin They should not be regarded as symptoms of the disease, hypertension being itself only a symptom, there is no evidence that it is the elevation in blood pressure that produces such early manifestations An analysis of 100 unselected out-patient records of hypersensitive cases, 53 of which were supplemented by a personal study, showed that in 82 per cent definite symptomatic relief was obtained by the use of simple suggestion in a group of 40 patients That such early symptoms were of a psychoneurotic nature is shown also by the fact that they are relieved by the removal of environmental difficulties or the achievement of adjustment thereto, by sedatives, or by suggestion Such early associated symptoms would appear to be due to the patient's emotional mal adaptation rather than to organic changes While the fundamental process concerned is not clear, it is probable that constitutional influences and endocrine disturbances contribute to lessen a hypersensitive patient's psychic and physical capacity for withstanding the stress and strain of life

99 Acute Benign Lymphocytic Meningitis

J FOURNAUD (*These de Paris*, 1931, No 122) records six illustrative cases in patients aged from 16 to 35, 4 were males and 2 females, and all suddenly developed symptoms of acute meningitis In each case the diagnosis of meningitis was confirmed by lumbar puncture, which showed considerable increase of albumin in all but one case, and more or less marked lymphocytosis The cerebro spinal sugar content was increased in two cases, normal in one, and not examined in the rest Hypertension of the cerebro spinal fluid was noted in several instances The resemblance to tuberculous meningitis was increased by the presence of photophobia, diplopia, hyperaesthesia of the skin, and hemiplegia In no case, however, was the tubercle bacillus found, although the cuti reaction was positive in two cases Syphilis could be excluded owing to the absence of a history of infection and of clinical or serological evidence of the disease An abortive attack of poliomyelitis was unlikely, since there was no epidemic of that disease, and none of the cases developed characteristic paralysis A mild form of cerebro-spinal fever was almost improbable Fournaud concludes that every clinical and laboratory test should be employed to determine the cause of a lymphocytic meningitis, the tuberculous nature of which has not yet been proved One should often avoid giving a definite prognosis in a case which at first sight appears to be one of tuberculous meningitis

100 G YOVANOVITCH (*Bull Office Internat d'Hyg Publ*, April, 1931, p 675) also records three cases of acute benign meningitis, with a lymphocytic reaction, which recently occurred at Belgrade The cerebro-spinal fluid in each case showed hypertension, and a moderate increase of albumin and sugar There was well marked lymphocytosis The Wassermann reaction was negative No tubercle bacilli or other micro organisms could be found in the fluid, and all the patients made uncomplicated recoveries

101 Congenital Haemorrhagic Telangiectasia

H M HICKS and ELIZABETH KNOX (*New York State Journ Med*, June 1st, 1931, p 687) report two cases of congenital haemorrhagic telangiectasia and review the literature relating to the previously recorded 50 families presenting the disease Telangiectases on the skin and mucous membranes, severe epistaxis, and a similar history in other members of the family constitute the main characteristics In the first case here recorded a man, aged 42, gave a history of epistaxis since early childhood, and complained of a severe attack lasting six days There was no history of alcoholism, syphilis, or other disease A brother and sister, his father, paternal uncle, and grandmother suffered from the complaint, but one sister and three other brothers were free The blood showed a secondary anaemia, the bleeding and clotting times being normal The nose was packed and the patient was transfused, but the haemorrhage recurred upon the removal of the packing Two tubes containing 25 mg of radium each were inserted in each nostril, and both were packed with iodoform gauze for twenty four hours, the epistaxis subsequently was much less frequent and severe The second patient, a man aged 55, was admitted suffering from secondary anaemia, cardiac dilatation, and myocardial insufficiency He gave a history of attacks of epistaxis since early childhood The nostrils were filled with dried blood The lips, tip of tongue, soft palate, and nail beds showed numerous small telangiectatic areas, while the laryngo cope revealed similar areas over the left arytenoid His mother and a brother had suffered from frequent epistaxis The blood smear was that of a secondary anaemia, and the Wassermann reaction was negative The authors remark that this disease is transmitted by both men and women The epistaxis is frequently present from childhood, but the telangiectases are not obvious until the age of 15 to 20 The condition usually becomes more marked in middle life

102 Meningeal Spirochaetosis without Jaundice

M LAIGNEL-LAVASTINE, Y BOQUIEN, and CH PLUMARTIN (*Bull et Mem Soc Med des Hop de Paris*, May 25th, 1931, p 802) report the case of a man, aged 33, admitted to hospital with severe headache and cerebral vomiting which had lasted for twelve days On examination there was found stiffness of the neck, Kernig's sign, intense injection of the conjunctiva with photophobia, pupils reacting normally to light and accommodation, herpes on the inner surface of the left upper eyelid, normal tendon reflexes, extensor reflex, normal liver and spleen, enlarged epitrochlear glands, a pulse rate of 60, some bronchitis, no pyrexia or jaundice, cutaneous hyperaesthesia, and well marked tache cérébrale The patient

was employed on construction work on the underground railway, in galleries infested with rats. The cerebro-spinal fluid was turbid, and contained 400 cells per c.mm., of which 59 per cent. were polynuclears and 41 per cent. lymphocytes. Albumin was present, and the Wassermann reaction was weakly positive. The blood-serum diagnosis of spirochaetosis was strongly positive. Inoculation of the cerebro-spinal fluid and the urine into a guinea-pig was negative, as was the direct examination of these fluids for the spirochaetes. The stiffness of the neck, Kernig's sign, and the headache disappeared after two days in hospital, but the patient had severe night sweats three weeks later, though his temperature continued normal. His subsequent convalescence was uneventful. The authors comment on the novelty of the source of infection in this case. The variety of the symptoms delayed recognition of the infecting agency.

103 Herpes Facialis following Antityphoid Vaccination

H. Gounelle (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, May 11th, 1931, p. 718) states that out of 320 soldiers inoculated with T.A.B. vaccine 70, or nearly 22 per cent., developed herpes facialis, which in one case was haemorrhagic. Herpes as a sequel of antityphoid vaccination is a well-known occurrence, and has received special attention from ophthalmologists owing to the serious results of involvement of the cornea. About a dozen examples of herpetic keratitis have been described by Morax, Gloagen, Rousseau, Bussy, Le Roux, and Aubineau, following the use of T.A.B. vaccine.

104 The Tuberculin Reaction in Typhus Fever

C. J. Wu and H. A. Reimann (*Nat. Med. Journ. China*, April, 1931, p. 210) performed the intracutaneous tuberculin test in twenty Chinese patients, aged from 20 to 30, who had been admitted to hospital with typhus fever. None of them had active clinical tuberculosis. It was found that only four gave a positive reaction during the febrile period. When, however, the test was repeated in convalescence, 12 showed a positive reaction, and the four patients who had reacted during the febrile period gave a slightly more intense reaction in convalescence. The behaviour of the intracutaneous tuberculin reaction, therefore, in typhus is similar to that seen during measles, influenza, and other acute infectious diseases.

Surgery

105 Subphrenic Abscess

H. P. Brown, jun. (*Annals of Surgery*, May, 1931, p. 1075) describes subphrenic abscess as one of the less frequently encountered complications of peritonitis; he reports 18 cases which occurred between 1910 and 1931. Of these, seven cases followed a perforation of an abdominal viscus, but the author points out that the condition may also result from an abscess of the spleen, kidney, pancreas, or spine, or from trauma, pyaemia, and distant foci of infection. It may also be a sequel of infection above the diaphragm, such as pneumonia, empyema, lung abscess, and osteomyelitis of the ribs. When the stomach, pancreas, or spleen is the primary focus, the abscess is usually left-sided; in most other cases it is found on the right side. Surgical diagnosis can be based on a history of preceding infection, leucocytosis, more or less localized tenderness with fullness and induration over the area involved, toxic condition of patient, a temperature range indicating the presence of pus, *x*-ray examination, and exploratory puncture. In most of the cases reported the subphrenic abscess followed a previous operation; five had had appendicectomies with drainage, two followed perforation of a peptic ulcer, two were subsequent to a cholecystostomy, one arose after a caecostomy, one as a sequel to puerperal fever with secondary abscess of the spleen, and one case followed an abdominal exploration. In only six instances had there been no previous operation. The average time for the subphrenic abscess to occur after the original operation is estimated at between two to three weeks, although frequently the condition is not recognized immediately. The surgical approach to the abscess depends upon its origin and location; when the source is retroperitoneal the best approach is from below the diaphragm; when the abscess occupies one of the anterior supra-hepatic spaces, presenting in the upper abdomen, the trans-abdominal route is the method of choice. In cases presenting on the upper right aspect of the liver, resection of the tenth or eleventh rib, with walling-off of the pleural cavity from the drainage tract, and direct drainage through the diaphragm, has given the best results. There were eight deaths in the series, a mortality of 44.4 per cent.

106 Post-traumatic Renal Calculus

I. Dubner (*Deut. med. Woch.*, May 15th, 1931, p. 851) refers to recently recorded cases of renal calculi formed around blood clots resulting from renal injury. He describes the case of a youth, aged 18, who was knocked down by a tramcar and dragged for some distance. The skin of the right loin was lacerated, and there were abrasions of the right thigh and knee. He remained in hospital for seven weeks. Three months later he had occasional pain in the right iliac fossa, which was aggravated by walking or climbing stairs; it was worse after meals, and appendicitis was diagnosed. There was slight pain on pressure over the right kidney and ureter; the left side was normal. Leucocytosis was present, and the urine contained albumin and erythrocytes. The results of examination of the right kidney, renal function test, cystoscopy, and pyelography were all negative. The temperature subsided, but an occasional pricking sensation in the right flank persisted. He was discharged after nearly six months' stay in hospital, but six months later definitely localized colicky pains occurred in the right renal region, and he was readmitted. A skiagram showed the shadow of a calculus in the right renal pelvis, and cystoscopy indicated a normal bladder. Pyelography confirmed the diagnosis of right renal calculus; pyelotomy was performed, and the stone was removed in two portions It was as large as a pea and contained old blood clot, evidently resulting from the renal injury eighteen months previously.

107 Bile-duct Drainage in Diabetes and Cholelithiasis

P. Harvier and J. Caroli (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, April 17th, 1931, p. 616) comment on the frequent association of diabetes and cholelithiasis. Recent observations suggest that diabetes may be secondary to cholelithiasis, and that their association is becoming more frequent. In all their cases pancreatic lesions were found. A woman, aged 45, had gall-stones; when first seen glycosuria was absent. Nine months later a large pancreatic cyst was discovered containing more than 5 pints of fluid. The gall-bladder was full of calculi, and a stone was lodged in the common duct. Glycosuria did not appear until a year after the first attack of colic, but severe progressive diabetes developed later. Another woman, aged 40, had chronic cholecystitis and slight pancreatitis. Signs of peritonitis necessitated an operation, and a necrotic pancreatic abscess and many biliary calculi were found. After recovery from the operation the patient had considerable glycosuria. The authors have had a case of gall-stones associated with diabetes and chronic hepatitis. Cholecystectomy, followed by prolonged drainage of the bile ducts, relieved the biliary symptoms, and the glycosuria and hepatitis disappeared. They believe that the theory that hepatitis is the origin of disturbance of carbohydrate metabolism is confirmed by the parallelism between the relief of biliary symptoms and the disappearance of the diabetes under surgical treatment, and also by the frequency with which transient glycosuria follows an attack of hepatic colic. The liver is always damaged in cholelithiasis, as has been shown by biopsies performed during operation. It has been suggested that, side by side with pancreatic deficiency, hepatic lesions occurring in the course of a calculous cholecystitis may play a part in the production of so-called "secondary" diabetes; this is confirmed by the second case in the authors' series.

108 Recklinghausen's and Paget's Diseases

Though many pathologists believe, on anatomical grounds, that there exists an intimate relation between the diseases named after Recklinghausen and Paget, J SNAPPER (*Ann de Med*, March, 1931, p 201) points out that in spite of the fact that both are characterized by a fibrous osteitis, there are marked differences between them In Paget's disease, which usually commences after the age of 45, the lesions are localized in the tibiae, pelvis, and cranium, the cortical layer of the bone is thickened, and the bones show clear striae Symptoms of hyperparathyroidism are absent the calcaemia and phosphataemia are normal, and the urinary and faecal calcium excretion varies within normal limits Parathyroid adenomas are never noted In Recklinghausen's disease—a disease of the young—the osseous cortical layer is progressively thinned by a marked resorption, and the remaining lamellae are traversed by fibrous tissue Multiple cysts develop throughout the skeleton, these contain giant cells, which are often mistaken for those of sarcoma, though they are benign proliferations of the normal medullary giant cells Symptoms of hyperparathyroidism are present—hypercalcaemia, hypophosphataemia, and an excessive urinary excretion of calcium Parathyroid adenomas are almost always found Snapper records three cases of Recklinghausen's disease in one, cure followed the removal of a parathyroid adenoma, in a second, this operation had to be supplemented by the administration of irradiated ergosterol while in the third, a slight case, considerable improvement was obtained with ergosterol, lime, and ultra violet rays No result followed the removal of both parathyroids in two cases of Paget's disease

109 Attenuated Forms of Acute Pancreatitis

R THOULUC (*These de Paris*, 1931, No 8), who records two illustrative cases, states that in addition to the haemorrhagic form of acute pancreatitis, in which the symptoms were well marked and characteristic, there are attenuated forms in which the initial symptoms rapidly improve and the clinical picture is extremely indefinite Accurate diagnosis is very difficult, and hitherto the condition has hardly ever been recognized before operation Although spontaneous recovery is possible operation appears to be the best treatment, followed by drainage of the pancreatic region Thouluc's patients were a woman aged 58 and a man aged 40, both made good recoveries after laparotomy and drainage

110 Recurrent Necrosis of Pancreas

A BALOG (*Zentralbl f Chir*, May 30th, 1931, p 1372), who records an illustrative case, states that recurrence of necrosis of the pancreas is a rare event, though examples have been recorded by Beer, Elving Coenen, and Hahn Balog's case was unique in that three recurrences occurred in the course of two months The patient was an obese woman aged 52, who had suffered from gall stones for several years The patient recovered from the first attack without an operation, this being contraindicated by the presence of pneumonia, but operations were performed in the three subsequent attacks, death ensuing two days after the last operation

111 Amicrobic Pyuria

P BAZY and P OLDARD (*Journ d Urol*, April, 1931, p 321) affirm that there are pyurias which are not tuberculous and in which microscopical and cultural examinations and animal inoculations are negative, the term amicrobic is preferred to aseptic They are divisible into two groups the intermittent, in which micro organisms are intermittently found in the urine, and the continuous, in which they are always absent Three cases illustrative of the first group and eleven of the second are recorded The intermittent disappearance of bacteria is stated to be due to an ill defined process of "auto sterilization" Pyuria may be of mechanical (urinary gravel or crystals), chemical, or infective origin In the last named the micro organism, passed rarely in the urine and found only after multiple examinations, is probably *B coli* or the staphylococcus and it also undergoes "auto sterilization Moreover, cases may be attributable to some unknown organism, undemonstrable by present means of examination Pyurias due to unilateral lesions also occur, as in tuberculosis or syphilis, and such conditions must be considered The authors emphasize the fact that in cases of amicrobic pyuria, especially in those with unilateral renal lesions, the results of animal inoculation should be awaited before resorting to operation, such as nephrectomy

112 Transvesical Prostatectomy

S RICHTER (*Upsala Lakarefor Forhand*, May 22nd, 1931 p 147) records observations on 425 cases of transvesical prostatectomy performed at the Linkoping Hospital during the period January 1st, 1916 to June 30th 1930 among 682 prostate cases The majority of the patients were between the ages of 71 and 75 years 105 were 81 years old or more In 372 cases the tumour removed was benign in 42 it was malignant, while in 5 no tumour was present Parasacral anaesthesia was employed and was effective in 98 per cent The mortality was 9 1 per cent In four instances death was due to intercurrent diseases, in three to epididymitis, in one to haemorrhage in one to pulmonary embolism, and in twenty six to the primary disease in conjunction with arterio sclerosis, myocarditis, or broncho pneumonia Vasectomy was performed 204 times to prevent epididymitis Owing to the frequency of carcinoma of the prostate, which occurred in 14 8 per cent of the present series, the difficulty of diagnosis, and the gravity of the prognosis in well-developed cancer of the prostate, Richter recommends that in all doubtful cases a radical operation should be performed

Therapeutics

113 Lipo-soluble Bismuth in the Treatment of Syphilis

A SCHWARTZ (*Presse Med*, June 3rd, 1931, p 809) ascribes to Fournier the chief credit for the evolution of bismuth therapy in syphilis Up to 1924 the results were variable and inconstant, because an emulsion and not a solution of a bismuth salt was used the rates of absorption and excretion were variable, and rendered the treatment less advantageous in comparison with intravenous arsenic Since 1924 lipo soluble salts have been used with excellent results, and in 1927 Fournier finally approved as the best the organic basic lipo-soluble salts, in 1930 he published details of a procedure indicating variations of dosage according to the general health of the subject For cases in the primary or secondary stages, a first series of twelve injections, each equivalent to 8 cg of metallic bismuth, are given intramuscularly, three in the first, and two in the following weeks one third of the cases should become sero negative after this series After a month's rest a further one third should be negative, and after a second series of injections the remainder, with rare exceptions should become so After one month's rest a third series is given, and after three months' rest, a fourth For several years two series are given in each twelve months spaced out with injections at five-day intervals During the treatment stomatitis must be watched for, and treated if it occurs, by local application of novarsenobenzol Schwartz reports, after three years experience, that accidents are extremely rare Stomatitis should not occur with proper oral hygiene and albuminuria never if the dosage is varied according to the general physical condition arterial embolism is a possible complication, but one of great rarity He has found the immediate results on primary and secondary lesions comparable to the best obtained with arsenical treatment and has not yet failed to make them disappear after the first series of injections All patients treated in the pre serological stage have remained negative and most have had only one or two series of injections 80 per cent of cases with positive Wassermann reactions have become negative after one series, and the rest after two series Most cases of serological relapse were insufficiently treated at the start or defaulted from observation for some months after one series Persistently sero-positive cases previously treated with arsenic sometimes become negative under bismuth treatment, such cases are said to be very rare

when bismuth is used from the start. Schwartz holds that bismuth is the drug of election for the treatment of syphilis, giving as good or better results than arsenic, with far less risk; he thinks that arsenic should now be reserved for the rare cases of bismuth-resistance.

114 Treatment of Hypertension

D. Riesman (*Journ. Amer. Med. Assoc.*, April 4th, 1931, p. 1105) regards hypertension as a disease of American life, rather than as an individual disorder, and insists that little improvement can result until more leisure is introduced into the average day's programme. In the treatment of hypertension the patient's fears must be quieted, since anxiety can raise both the normal, and the more sensitive abnormal, blood pressure. Attention should be paid to chronic constipation, infected teeth, and other sites of focal infection, but no measure is so successful and generally applicable as rest, either complete or partial. Physical exertion must be eliminated, and a week's rest in bed will always indicate the extent of the effect obtainable in this way. If the symptoms are fairly severe and denote commencing cardiac fatigue, the rest in bed must be considerably prolonged. It is rarely necessary to remove the patient completely from his business; such a step only tends to make him a confirmed hypochondriac, and may shorten his life; it is usually sufficient to cut down the hours of work. Riesman believes in reducing the salt intake to a minimum, and in restricting the use of tobacco in hypertensive patients who have had cardiac pain, though in others it is a useful sedative for "frayed nerves." Of the medicinal remedies, he has found glyceryl trinitrate and erythrol tetranitrate the most valuable. Sodium nitrate has not yielded, in his experience, equally good results, while amyl nitrite, though potent, is disagreeable, and should be reserved for special emergencies. Potassium thiocyanate in 1½ grain doses, three times a day, for five days, then twice daily for a week, and then once daily, has sometimes given satisfactory results. Bleeding is useful, and the iodides are undoubtedly effective in the case of syphilitic patients, though not in others.

115 Treatment of Peripheral Vascular Lesions

R. H. Smithwick (*New England Journ. Med.*, April 23rd, 1931, p. 845) discusses the value of foreign protein, and of alcohol injection of sensory nerves, in the treatment of peripheral vascular lesions. Typhoid vaccine was employed as the foreign protein, and doses of 50 to 250 million bacilli were given intravenously. By this means was produced an initial retardation of the circulation in the extremities; a rigor usually followed, accompanied by fever of about 103° F., and a very greatly increased peripheral circulation. Extremities previously cool and cyanosed became warmer, dry, and of better colour. During the initial phase of the reaction, thrombosis occurred on two occasions, but only in patients afflicted with a senile type of obliterative vascular disease. This treatment was therefore never given to patients over the age of 50, and when it was employed the extremities were previously heated to 100° F. by blankets and hot-water bottles. In patients experiencing the severe pain of gangrenous ulceration secondary to obliterative vascular disease, the method of desensitization by alcohol injections was employed. It was possible to anaesthetize the entire foot and ankle by injections into the posterior tibial, superficial peroneal, deep peroneal, saphenous, and sural nerves. Frequently the area involved could be blocked by injecting two or three of these nerves. By exposing and injecting the nerves six inches above the ankle and using a minimal quantity of alcohol, adequate healing was assured; it was found also that the circulation of the desensitized area was increased, presumably owing to inhibition of the vaso-constrictor supply. A further advantage of this method of treatment was that proper dressings might be applied when pain had been thus eliminated, so reducing the liability to infection and thrombosis of the capillary circulation. Patients who otherwise would have been subjected to a major amputation were frequently restored to useful activity after a few months of this treatment.

Neurology and Psychology

116 Arterial Angioma of the Brain

R. M. Stewart and W. Ross Ashby (*Journ. Neurol. and Psychopathol.*, April, 1931, p. 289) report a case of arterial angioma in a woman, aged 32, the condition being associated with complete absence of the corpus callosum. At the age of 19 she had had a blow on the head, which was followed later by the appearance of a bunch of enlarged veins on the forehead, severe headache, defective gait, and paralysis of the right upper limb. At 26 epileptic fits began, eventually assuming the grand mal type; they were associated with dementia, and the patient died convulsed at 53. A large angioma was found to occupy the mesial surface of the frontal convolutions of the left cerebral hemisphere; it was in the area of the anterior cerebral artery, and was composed of very large veins and arteries which showed proliferation of the intima, absence or splitting of the internal elastic membrane, imperfect development of the tunica media, and thickening of the adventitia. Abnormal and aberrant vessels were found in the mid-brain, the falx cerebri was much thickened, and the corpus callosum was entirely absent. Commenting on the case, the authors remark that the angioma would appear to have been in existence for thirty-four years. The two most important symptoms of this condition are increased extracranial vascularity and an audible intracranial bruit; auscultation of the skull is emphasized as being an essential part of a routine neurological examination. The hypertrophy of the vessels is explained by the increase in blood volume which, as Holman has demonstrated, is always associated with the establishment of an arterio-venous fistula. Exophthalmos is another important sign; it is generally unilateral, but in the present case was bilateral, presumably because of the mesial situation of the angioma.

117 The Nature and Treatment of Dementia Praecox

According to R. G. Hoskins (*Journ. Amer. Med. Assoc.*, April 11th, 1931, p. 1209) dementia praecox is a persistent dream state—a defensive reaction in a sensitive human being against a feeling of personal failure. It results from the recognition of inability to reach the personal standards that the patient has accepted for himself, and is characterized by a sense of isolation associated with panic, loss of hope, evasiveness with projection and grandiose delusions, or by simple acceptance of inferiority. There is a fundamental intolerable loss of self-respect. To cure such a patient he must be brought back to reality, and be sufficiently interested to stop his dreaming. His self-respect can be increased by correction of his personal standards, if erroneous, by encouraging personal neatness and cleanliness; by treating him respectfully, remembering that he is insane because he is sensitive; by stimulating him to do things which he himself will respect, helping him to be helpful to others; and by instilling into him the realization that he does not need the form of self-protection he has adopted. Hoskins states that dementia praecox is responsible for filling one-fifth of all the hospital beds in the United States, involving a daily expenditure of about one million dollars. He maintains that treatment on the lines suggested is far superior in its effects to the various other psychotherapeutic procedures that have been based on more profound theorizing. The essential point is the attraction of the patient from his self-inflicted isolation to an increasing interest in community life.

118 The Reactive Manic Episode

W. McC. Harrowes (*Journ. Mental Sci.*, January, 1931, p. 127) criticizes Bleuler's statement that reactive mania is unknown, and reports two cases in which excitement with manic features and toxic phenomena appeared; recovery ensued in both cases. The etiology of the nervous processes concerned is discussed, with special reference to prognosis. The author emphasizes the point that the individual makes adjustments of two kinds normally: long-term adjustments, with subservience of the present to the claim of the more distant future; and

short term adjustments, dealing with the more immediate present In one of his cases the first attack came as an incident in a typical long term situation in a young woman faced with a life of uncongenial work involving serious conflicts, a long drawn out psychosis followed with excitement of the manic type In his other case the disorientation, though complete, was relatively brief, at the end of ten weeks full recovery was reached, though the patient had a complete amnesia for the whole illness from the time of the sudden shock which had initiated the manic episode The author adds that careful evaluation of the total series of events in such morbid conditions will give valuable help in determining whether the case is of the long term or short term nature He adds that there is still more to be done in the way of investigating the relation of toxic factors to neurotic and psychotic conditions

Obstetrics and Gynaecology

119 Tuberculosis and Sterility

According to H HOPPNER (*Zentralbl f Gynak*, April 4th, 1931, p 1269) sterility in tuberculous subjects may be due to (1) tuberculous lesions of the Fallopian tubes, (2) tuberculous lesions of the ovaries, (3) a destruction of the ovarian—and therefore of the uterine—cycle, in the absence of a gross anatomical lesion of the ovaries, which show on histological examination that many of the primordial follicles have been destroyed before puberty, and (4) to the presence of miliary tubercles in the superficial layers of the endometrium only Clinical examples of the last group are cited in which repeated curettings from sterile patients showed endometrial tubercles in some cases conception followed curetting or *x* ray therapy It must be admitted, however, that in rare cases the lodgement of the fertilized ovum in a tuberculous endometrium is possible, proof of this is difficult, but such nidation in a tuberculous Fallopian tube has been demonstrated Such a pregnancy, leading to rupture, is here described and illustrated

120 Uterine Epithelioma and Sarcoma

The coexistence of two benign uterine tumours, or of one malignant and one benign growth, is not infrequent, but the simultaneous development of two malignant tumours of the uterus is rarely noted R LEROUX and M PERROT (*Bull de l'Assoc Franç pour l'Étude du Cancer*, April, 1931, p 283) record such a case The structure of sarcomatous tissue is very polymorphous, while that of epitheliomas, whether complicated with sarcoma or not, is of the glandular type, and a case of Malpighian involvement has not yet been reported Examination of the uterus after hysterectomy, in the present case revealed multiple benign fibromyomas, glandular and Malpighian epitheliomas, leiomyosarcoma, fibroblastic sarcoma and sarcoma with large round cells apparently derived from cytogenic chorion The histology of these is described, and various points in relation to them are discussed The rarity of such complex neoplastic formation in the one organ is emphasized, and the authors suggest as its cause a dysembryoplasia The presence of growths in the utero sacral ligament renders such a hypothesis very plausible

121 Permeability of the Foetal Fallopian Tubes

N MARKOFF (*Gynecol et Obstet*, April, 1931, p 323) points out that there are important and interesting exceptions to the general rule that the genital life of the female except in cases of uterine infantilism or defects of the spermatozoon, forms the basis of the sterility which is acquired after infections Aburel, in post mortem examinations of two newborn infants who had acute vulvo-vaginitis and died of peritonitis, found a purulent metro salpingitis, he believes that, if the infants had survived, the condition would have become chronic and impermeability of the tubes have developed Vulvo vaginitis, he adds, is not exceptional, and various authors have shown that the infection in such cases may be propagated along the upper genital passages, and cause peritonitis Having observed many cases of sterility without infantilism or history of previous infection, Markoff examined sixteen embryos of ages ranging from four to nine months He found that in many cases impermeability of one or both tubes was present, he concludes that there is a congenital tubal impermeability which can be the cause of sterility These findings agree with those of Boutowski in twelve cases Markoff considers that this congenital impermeability is due to defective embryonic development, and not to inflammatory infections during intrauterine life, and that the findings here recorded throw a new light on the pathogenesis of female sterility

122 Treatment of Delayed Post-partum Haemorrhage

PLACINTIANU (*La Ginecol* April, 1931, p 193) discusses the treatment of delayed haemorrhage after confinement Whether it is associated with retained placenta or not, post partum haemorrhage is a complication which exposes the patient to great risks that arise from the grave anaemia which reduces the patient's resistance, and also from the fact that haemorrhage may actually be a sign of infection If it is impossible to make a diagnosis of retention by other means, vaginal examination with the most stringent aseptic precautions may be employed In cases of haemorrhage with retention of placenta, when the placenta is free in the utero cervical canal, a careful, slow, and aseptic digital extraction may be employed In cases of definite adherent placenta, hysterectomy becomes necessary In all cases of secondary haemorrhage, medical, local, and general treatment must be adopted, and for many cases does actually suffice For the more serious forms abdominal hysterectomy with Mikulicz drainage is the only advisable procedure

123 The Zondek-Aschheim Test and Hydatidiform Mole and Chorion epithelioma

F VOZZA (*Ann di Ostet e Ginecol* March 31st 1931 p 267) emphasizes the importance of the Zondek Aschheim pregnancy reaction in the diagnosis, treatment and prognosis of hydatidiform mole and chorion epithelioma He accepts the view that the hormone responsible for the reaction is chiefly of placental origin and is usually secreted and excreted in greatly increased amounts in such cases In eighteen personal cases of vesicular mole Vozza obtained a positive Zondek Aschheim reaction, and as much as 100 000 mouse units in a litre of urine Fourteen patients still had a positive reaction ten days after expulsion of the mole but after a further three weeks it had become negative in those who could be followed up Performance of the test in patients who have expelled vesicular moles gives invaluable information concerning the possible supervention of chorion epithelioma Five cases are quoted from the literature in which curettings showed microscopical characters definitely pointing to chorion epithelioma, but in which the patients remained well in spite of radical treatment being withheld on account of a negative Zondek Aschheim reaction Curetting in chorion epithelioma is not without danger, and the pregnancy reaction in the urine probably forms a more reliable prognostic guide Vozza records in detail three cases of hydatidiform mole in which curettings revealed no trace of malignancy, but the persistence of a positive Zondek Aschheim reaction led to the performance of hysterectomy, examination of the uterus subsequently brought to light small intramural or other areas of chorion epithelioma Two of these patients have remained well, with negative urine reactions for some months since the radical operation the remaining patient, in whom the test remained positive died with metastases

124 Primary Epithelioma of the Fallopian Tube

G A CADET (*Thèse de Paris* 1931 No 124), who records a personal case maintains that the rarity of primary epithelioma of the Fallopian tubes is probably more apparent than real In the absence of a systematic histological examination a tubal neoplasm can easily be overlooked, and be mistaken for an ordinary inflammatory

lesion of the adnexa. The affection is almost confined to the period of the menopause, between the ages of 40 and 50. Unlike other forms of cancer, it is sometimes painful at the onset. The symptoms, which include pain of varying degree and situation, leucorrhoea, and menstrual disturbance, are not characteristic, but the presence of a sausage-shaped tumour, rapidly increasing in size, the absence of pyrexia, and the demonstration of an extra-uterine source of a haemorrhagic and purulent discharge, are suggestive of a Fallopian epithelioma. In view of the highly malignant character of the condition, early and extensive operation is indicated. Cadet's patient was a woman, aged 50, who was successfully treated by subtotal hysterectomy.

Pathology

125 Difficulties of Diagnosing Plague in Rats

W. Levinthal (*Zeit. f. Hyg. u. Infektionsk.*, May 22nd, 1931, p. 433) points out that, in the diagnosis of plague in rats, not only may the pseudo-tubercle bacillus give trouble, but also *B. coli*. He has recently examined a strain, identified as a plague bacillus, recovered from an epidemic among rats on a ship, in which apparently 68 out of a total of 182 rats died. In broth cultures this organism showed well-marked bipolar staining; it proved fatal to guinea-pigs in four days, though it was non-pathogenic grey rats. It was agglutinated almost to titre by an anti-plague serum. Closer examination, however, revealed that it was motile, that it produced gas in sugar media, and that it formed indol. The agglutinability of this *B. coli* strain by an anti-plague serum was found to be due to the fact that the serum had been prepared by injection of a horse, and that the agglutinins for the coliform bacillus were not specific agglutinins for *Past. pestis*, but natural agglutinins for *B. coli*. The strain was agglutinated by an antipneumococcal serum prepared from a horse, but not by one prepared from a rabbit, thus confirming the truth of this explanation. The author states that he has met with several recently isolated strains of *B. coli* which produced a plague-like disease in guinea-pigs—buboes embedded in haemorrhagic oedema—and which in the organs closely resembled the plague bacillus. Such organisms are not infective by the cutaneous route, and rapidly lose their virulence.

126 Effect of Dilution on Antiseptics

T. N. Seth and S. K. G. Dastidar (*Ind. Journ. of Med. Research*, April, 1931, p. 1211) have investigated the effects of gradual dilution on the properties of an antiseptic. They find that an increase in the dilution of an antiseptic which dissociates in solution causes a steady decline in its activity up to a certain point; beyond this there is a limited range in which further dilution definitely increases its relative effectiveness, while still further dilution again lowers its activity. Mercuric chloride, carbolic acid, and ethyl alcohol were used in varying dilutions, the relative powers of which in preventing the growth of *Staphylococcus aureus* were taken as the measure of their effectiveness. This was found to decline with progressive dilutions up to a point beyond which further dilution causes a marked recovery in the activity of the antiseptic. It would appear that the antiseptic action of substances which dissociate in solution depends upon two factors: (1) the influence of the undissociated molecules of the antiseptic on the organism, and (2) the influence of the ions of the antiseptic on the organism. At the higher concentrations the first of these predominates, and with increase in the dilution the number of undissociated molecules of the antiseptic diminishes. So long as the number of ions is insufficient to counterbalance the decline in (1) the effectiveness of the antiseptic as a whole steadily decreases. Beyond a certain point, however, the action of the antiseptic becomes again intensified, due to such an increase in (2) as more than counterbalances the decline in

127 The Presence of Foot-and-Mouth Virus in Vaccine Lymph

T. Van Heelsbergen (*Ann. de l'Inst. Past.*, May, 1931, p. 558) relates how, at the beginning of last year, some vaccine lymph coming from the State Vaccine Institute in Norway was used by Slagsvold to inoculate some cattle. Besides developing vaccinia, these animals showed signs of foot-and-mouth disease, and other animals in contact with them contracted this disease. Guinea-pigs inoculated into the paws with the vaccine lymph developed typical symptoms of foot-and-mouth disease, showing clearly that the vaccine itself must have been contaminated with the foot-and-mouth virus. The present author now describes experiments made by himself on this particular strain of vaccinia. Inoculation into a calf gave rise to a severe attack of foot-and-mouth disease, followed later by the appearance of vaccinia pustules. A second calf inoculated from the fluid in the vesicles developed foot-and-mouth lesions without any subsequent vaccinia lesions, indicating that the vesicular fluid did not contain the vaccine virus. In this way the foot-and-mouth virus was obtained in pure culture. A pure culture of vaccinia virus was obtained from the original contaminated vaccine by passage through cocks, the inoculations being made on to the comb. In two out of four birds a mild pustular eruption occurred, and material from these pustules inoculated on to the abdominal skin of a calf gave rise to typical vaccinia without any foot-and-mouth lesions. The purity of both strains was demonstrated by rabbit inoculations, and by cross-immunity experiments on calves.

128 Salt Excretion in Obesity

G. Kahlmeter (*Acta Med. Scand.*, April 28th, 1931, p. 107) states that purely endogenous or exogenous cases of obesity are probably not common, the condition arising from the association of both intrinsic and extrinsic causes. The endogenous factors are generally considered to be disturbances of several endocrine glands, or a faulty interaction between some, such interaction being probably regulated by the sympathetic nervous system. Organic and functional disturbances of the basal parts of the mid-brain (the seat of the sympathetic regulation) not infrequently cause obesity, and in this condition other sympathetic disturbances such as increased sugar tolerance and hyperhidrosis are noted. The author investigated the water and salt metabolism in fifteen cases of obesity and describes his tests. It was found in most instances after the salt tolerance test that there was a delayed excretion of the salt and water. Cardiac and renal disorders could be excluded as the cause of this retention, which, therefore, was presumably attributable to endocrine or sympathetic disturbance. Kahlmeter concludes that in certain cases of obesity the salt and water excretion is at fault, probably due to derangements of the sympathetic system or of certain endocrine glands, possibly the pituitary or liver, or both. He emphasizes the clinical value of recognizing this form of obesity, since restriction of salt in the diet is essential in treating such patients.

129 The Blood Picture in Infantile Tuberculosis

B. M. Hamil (*Amer. Journ. Dis. Child.*, May, 1931, p. 1023) records a study of the blood picture in this condition. The monocytes are increased above the normal figures in active tuberculosis; this is constant in severe tuberculosis, but not pathognomonic. The total lymphocyte count is decreased below the normal in all active types of tuberculosis, this decrease depending on the severity of the disease, the count increasing in the healing stage. The relation of the lymphocytes to the tuberculous process is more constant than that of the monocytes. Multiple lesions in different pathological stages, the tuberculin skin test, and ultra-violet irradiation, in cases of chronic and advanced healing tuberculosis, cause changes in the monocyte-lymphocyte ratio, which cannot then be depended on to indicate the state of the tuberculous process. No blood picture can in any case warrant a diagnosis of tuberculosis without the support of clinical evidence.

The **SPECIFIC OVARIAN HORMONE**
which normally controls and activates the menstrual cycle

SISTOMENSIN
standardised physiologically

dysmenorrhœa, menorrhagia, hæmorrhages of puberty and menopause, hypoplasia of the uterus, disturbances subsequent to menopause or oöphorectomy.

Tablets Ampoules

PROKLIMAN
(Sistomensin Compound)

Association of ovarian hormone with therapeutic agents for the prompt relief of the most pronounced troubles of menopause: cardiovascular and nervous troubles, hot flushes, headache, etc.

Tablets

Hydrosoluble Ovarian Substance

AGOMENSIN

causes hyperæmia of the female genital organs. Stimulates the function of the genital glands and menstruation.

Functional amenorrhœa, oligomenorrhœa, sterility, vomiting during pregnancy, etc.

RE-INFORCING THE ABDOMINAL MUSCLES WITHOUT UNDUE PRESSURE!

For those disorders of the abdomen that call for external support, Domen Abdominal Belts have very definite advantages. They give adequate support to the abdomen without setting up pressure to aggravate the patient's condition. And whether it is pregnancy or umbilical hernia, prolapsus uteri, or simply general support, there is a Domen Belt designed specifically for that condition. Domen Belts fit well, sit comfortably and do not get out of place. They leave the patient free and without embarrassment. Full particulars will be forwarded on receipt of your card or a telephoned request.

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS.

NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. LAMBERT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients who are suffering from incipient mental disorders or who wish to prevent recurrent attacks of mental trouble, temporary patients, and certified patients of both sexes are received for treatment. Careful clinical, biochemical, bacteriological and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical Bath, Plombieres treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit and vegetables are supplied to the Hospital from the farm, gardens and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard court), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56 Northampton) who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM.

HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary and Temporary Patients received.

Tel. 64117. *For terms etc. apply to the Medical Superintendent.*

BRITISH SPAS ARE BEST

and membership of the British Spas Federation is a guarantee of efficiency

AT British Spas, treatment is only given (except in a few minor cases) upon medical prescription.

At British Spas the staffs are educated and properly trained and, in some cases, medically trained and medically certificated.

Equipment and administration are thoroughly up to date and scientific. Every new treatment is tested and reported upon before being adopted.

British Spas are also remarkably fortunate as regards situation, scenic beauty and pure air. These factors, combined with the social amenities of a home town, aid the cure considerably.

BATH Hot Springs (120° F.) Radio-active. Royal Baths extensions now open.

BRIDGE OF ALLAN Saline Water. Rich Calcium Bromide and Iodine Content.

By Order of the House Committee,
CHARLES M. POWER, Secretary.

Metropolitan Borough of Poplar.

MALE ASSISTANT TUBERCULOSIS OFFICER AND ASSISTANT MEDICAL OFFICER OF HEALTH.

The Council of the Metropolitan Borough of Poplar invite applications for the above post from duly qualified and registered male Medical Practitioners, who are specially qualified in the diagnosis and treatment of Tuberculosis, and not over 40 years of age.

The person appointed will assist the Tuberculosis Officer, and, when necessary, carry out other duties in the Public Health Department under the direction of the Medical Officer of Health, and devote his whole time to the services of the Council.

Applicants should have:

(1) At least three years' experience in the practice of his profession.
(2) Spent in general clinical work a period of not less than 18 months, of which not less than six months have been spent in a hospital as a Resident Officer in charge of beds occupied by general medical and surgical cases, and
(3) Received special training for a period of not less than six months in the diagnosis and treatment of Tuberculosis.

A Diploma in Public Health is desirable.

The commencing salary will be at the rate of £550 per annum, rising by annual increments of £25 to £700 per annum.

The successful candidate will be required to pass a medical examination, and to contribute to the Council's Superannuation Fund.

Forms of application may be obtained from my office, and must be returned, together with a letter of application, and copies of three recent testimonials, in envelope endorsed "Male Assistant Medical Officer of Health," not later than Saturday, August 22nd next.

Canvassing members or Officers of the Council in any form will disqualify.

Council Offices, Poplar, E.14. H. E. DENNIS, Town Clerk.
July 28th, 1931.

County Borough of Dewsbury.

DEPUTY SCHOOL MEDICAL OFFICER AND DEPUTY MEDICAL OFFICER OF HEALTH.

Applications are invited from duly qualified and registered Medical Practitioners for the post of Deputy School Medical Officer and Deputy Medical Officer of Health.

Applicants should have had at least three years' experience since qualification. Experience in Eye work and Refractions is essential. The possession of the D.P.H., and previous experience in School Medical Inspection and the work of a School Clinic, and in Tuberculosis and Child Welfare, will be considered important additional qualifications.

The inclusive salary will be at the rate of £600 per annum. Particulars of the duties and conditions of appointment, together with application forms, may be obtained from Dr. R. M. GALLOWAY, Medical Officer of Health, Market Place, Dewsbury, to whom all applications, accompanied by copies of not more than three recent testimonials, should be delivered not later than Saturday, August 22nd.

Town Hall, Dewsbury. HOLLAND BOOTH, Town Clerk.
July, 1931.

County Borough of Birkenhead

PUBLIC ASSISTANCE COMMITTEE

RESIDENT ASSISTANT MEDICAL SUPERINTENDENT.

The Birkenhead Corporation invite applications for the appointment of Resident Assistant Medical Superintendent at the Infirmary and Institution, Tranmere, Birkenhead. The Infirmary contains 596 beds and the Institution 677 beds.

Salary after the rate of £450 per annum, rising by annual increments of £25 to a maximum of £550 per annum, together with the usual residential, etc., allowances.

The appointment is subject to the provisions of either the Local Government and Other Officers Superannuation Act, 1922, or the Poor Law Officers Superannuation Act, 1896, whichever is applicable.

Candidates must be duly qualified and registered under the Medical Acts, and have had experience in operative surgery, and must be capable of performing any emergency operation in the absence of the Medical Superintendent.

The appointed candidate may be required, at the discretion of the Council, to undertake such other duties of a medical or surgical nature in the Public Health Services of the County Borough as may be assigned to him.

Further information may be obtained from the Medical Superintendent of the Infirmary.

Forms of application, to be obtained from the Secretary, Public Assistance Offices, 5, Conway Street, Birkenhead (on receipt of a stamped addressed foolscap envelope), must be returned to the undersigned not later than Monday, August 17th, endorsed "RAMS."

Canvassing the members, directly or indirectly, will disqualify the candidate.
